Although the issue here is the modern financial debt of the Greek state, the Parthenon (Elgin) Marbles provide the framework on which similar actions and protests are built, precisely because they are considered to show the greatness of Greece due to its classical culture, which is diametrically opposed to the current image of Greece that Europe holds today (Plantzos 2012, pp. 159–160). The struggle for the restructuring of the Greek debt is considered as fair as the struggle of the New Acropolis Museum and the Greek state for the return of the Parthenon (Elgin) Marbles. The seminal difference between the two debts is that while the financial debt can potentially be repaid, the moral debt to the ancestors is never repaid (Hamilakis 2016). Thus, on the one hand, the Greek state and New Acropolis Museum bear the moral duty of preserving and promoting

the universal values of classical culture in Europe and the world, and on the other hand, Europe seems to have a moral debt to Greece precisely because it has built its modern ideals, democracy, speech, beauty, freedom, and morality on the classical culture (Plantzos 2012; Yalouri 2001). This view has the effect of reversing the roles of the lender and the borrower: while Greece is a modern European borrower, Europe must, in turn, repay its huge cultural debt to Greece, from which it borrowed the values of its own existence and the core of its constitution.

"Bottom-Up" Interpretations of the Parthenon (Elgin) Marbles

What the four axes that were analyzed so far, namely, that of absence, trauma, kinship, and debt, have in common is that the rhetoric expressed around them does not exclusively stem from the institutional administrators of the classical past, but it also comes from various groups of the Greek and foreign public who consider it a duty, a craving, a need, or a debt to protest, each one of them in a less or more ingenuous way, for the return of the Parthenon Marbles. In this case, there is no conflict between the "bottom-up" voices with the dominant national narrative, as these are in harmony with and reproduce the national rhetoric about cultural heritage, the classical past, and national identity. However, this reproduction is not neutral nor is a mere repetition of the national narrative. On the contrary, precisely because the groups of people who identify with the issue of the Parthenon (Elgin) Marbles return vary, their actions, the voices, the campaigns, etc. are also varied, without, of course, avoiding historical anachronisms, simplifications, populism, banal nationalism, and historical gaps.

Here, an important role for the performative dimensions of national identity and for the reproduction of the national discourse is, as already mentioned, played by *habitus*, which as a collective principle produces and builds cultural practices and cultural representations (Bourdieu 1977, p. 72, in Csordas 1990, p. 11). Habitus also exists at national level as the so-called national habitus (Loyal and Quilley 2004, pp. 130 and 138; Pickel n.d., pp. 4–5), stating the ideological practices that allow the verbal or tangible reproduction of national messages and connotations by the subjects (Billig 1995, p. 6). Events such as memorial practices, performances, celebrations, etc. promote the social cohesion of the national subjects and the desired cultural homogeneity. Especially through national cultural traumas, and the extraction of the Parthenon (Elgin) Marbles is such a collective trauma, narratives are created that are adopted by the subjects through socialization techniques and mnemonic politics. In this way, cultural trauma becomes part of the national habitus. Thus, a set of situations, behaviors, and practices, the so-called banal nationalism by Billig (1995), are formed and are not separate from the daily routine of the subjects but endemic to it, as the nation is indicated, performed, and signified daily through them in the life of its citizens (Billig 1995, p. 6).

In this context, as mentioned above, there is a plethora of national and international committees for the reunification of the Parthenon and for the return of the Parthenon (Elgin) Marbles (see for example the International Association for the Reunification of the Parthenon Marbles http://www.parthenoninternational.org/), as well as independent citizens' movements, some of them are individually organized and some others take the form of information and protest campaigns. Among the prominent ones is the *Bring Them Back* campaign for the return of the Parthenon (Elgin) Marbles. Arguing for the reunification of the monument, the campaign hosts a directed video (http://www.bringthemback.org/) on its website where, in a supposed news bulletin, a well-known Greek journalist interviews a middle-aged gentleman who bears the surname Elginiadis and appears to have removed the top of the Big Ben tower in London and have taken it to his home. The allegory is obvious, as are the arguments that follow from both sides, that of the interviewer and of the interviewee, and resemble those of the British Museum. The style of the video changes completely when a well-known Greek journalist who lives outside Greece appears extremely well dressed inside the New Acropolis Museum and presents in a scientific but simple way the issue of the return of the Parthenon (Elgin) Marbles.

The same campaign on its Facebook page hosts a video shot by the students of the 9th Primary

School of the district of Agios Dimitrios, Attica. A group of children wearing t-shirts with the *Bring Them Back* campaign logo is singing (https://www.facebook.com/BringThemBack/) for the return of the Parthenon (Elgin) Marbles to the rhythm of Tanita Tikaram's song *Twist in my Sobriety.* The adapted lyrics, in a very upfront manner, serve the national imagination as they adopt religious terms (resurrection) but also terms of romanticism (attic light): "In the museum we clearly demand/to be returned to the light of Attica/to be once again resurrected the Parthenon's marbles/to be returned into the light", perceiving history in the familiar linear way: "history is a river and time is flowing."

Another independent, voluntary campaign for the repatriation of the looted Greek antiquities, the so-called I AM GREEK AND I WANT TO GO HOME campaign, was initiated by the photographer and musician Mr. Kalogeropoulos (http://www.dinfo.gr/i-am-greek-and-i-wanna-go-home/), who created a series of photographs and videos, where different sculptures and reliefs speak to the viewer in first person asking them to return to their homeland: "You can steal a statue, but you cannot steal my place of origin. I am Greek, and I want to come home", "I was born in Greece, my sisters are there. I am Greek, and I want to go home", "Citizens of the world, I am being held hostage. Help me get home, in Greece." The appeal to the emotion is evident and is successfully achieved precisely because of the personalized, almost animistic, approach of material culture which shares with the public feelings of sadness, nostalgia, and injustice under the sounds of epic, dramatic music.

On the 7th day of July 2014, a group of artists organized a short performance in the British Museum. The conductor Mr. Orphanides, the composer Mr. Pavlidis, the soprano Ms. Theodoridou, and six women "six beautiful Greek women dressed in white as 'other' Caryatids, entered the British Museum looking for their lost 'sister' [. . .]. The team [. . .] began to search for the lost Caryatid in the museum. When they found her, their emotions were indescribable" (https://goo.gl/FWlNMr).

This initiative communicates feelings of despair, sorrow, indignation, and distress to the international audience through a physical performance that invokes family ties and doesn't avoid reproducing traditional schemes of interpretations of the past.

These bottom-up actions shed light to "informal" aspects of the personal relationship between subjects, archaeological objects, and the past, thus expanding the concept of cultural diplomacy and its practices through embodied, multisensory, and participatory ways. Hamilakis (1999, p. 304) rightly points out that "bottom-up" approaches illuminate the complex processes of the production of archaeological discourses, and through the negotiation of social roles and identities, it can be a useful tool compared to legal processes, institutions, and the official frameworks for cultural heritage management.

Epilogue

At the level of cultural diplomacy in relation to the repatriation of the Parthenon (Elgin) Marbles, it is noted that the rhetoric of both the Greek state and the informal voices has begun to be differentiated and to take into account other parameters as arguments of claim. As stated by Hamilakis (2007), since the early 1990s, the Greek government and recently the New Acropolis Museum have put less emphasis on the argument of ownership of the Parthenon (Elgin) Marbles, which is based on claims of national continuity, and promote the argument of the reunification of the monument as a symbol of world heritage and the imperative need for the Parthenon (Elgin) Marbles to be returned as the landmarks of Western civilization.

Respectively, the arguments that relate to cultural diplomacy and focus on the New Acropolis Museum are expressed by informal actors and individual "bottom-up" initiatives seeming to have embraced the aforementioned change with enough originality. Thus, cultural diplomacy in relation to the return of the Parthenon (Elgin) Marbles seems to escape the traditional forms of linguistic, religious, and racial perceptions of identity and, instead, to include new, expanded identity approaches that are articulated in psychological, social, biological, and behavioral terms. It is in this context that the Parthenon (Elgin) Marbles are ascribed human qualities.

The sculptures appear to talk, to cry out, to yearn, to hurt, and to call their abducted siblings in London, in an obvious attempt to "speak the same language" as the public, the national subjects, the modern "Philhellenes," the diplomatic communities, and the visitors to both the British Museum and the New Acropolis Museum. The personification of antiquities and the attribution of human characteristics and emotions to the Parthenon (Elgin) Marbles facilitate the process of familiarizing subjects and objects, a process which consolidates their meanings to the point of idealization. Unification demands are further reinforced through the sense of victimization and trauma, since the Parthenon (Elgin) Marbles are perceived as wounded humans. Words such as fragmented, dismembered, wounds, and references to destruction, looting, and rape emotionally charge the communication between the public and the past, emphasizing on the unfulfilled claim for the Parthenon (Elgin) Marbles' repatriation (Stefanou 2011).

Through these cultural and embodied constructions, the boundaries, the practices, and the ways of communication of cultural diplomacy are expanded: they include a variety of ways for transmitting messages; they utilize modern means of communication and social networking to be heard; they involve more subjects/actors who identify with the issue of the return of the Parthenon (Elgin) Marbles and shape their own rhetoric; they invoke human emotions by speaking directly to the thymic and the volitional parts of their audiences' soul; and they draw directly from the current sociopolitical circumstances, offering new readings of the past and its material culture.

Therefore, these new formations of cultural diplomacy around the Parthenon (Elgin) Marbles, within and outside the New Acropolis Museum, function successfully both at national and supranational levels, as they are informal attempts to manage archaeological remains, promote an expanded, all-inclusive discourse about the past, and show a more personal, embodied, and performative relationship with the material culture and the museum space. The main issue at stake now is whether the Parthenon (Elgin) Marbles should continue being on display in the universal British Museum, treated as aestheticized masterpieces of world art, or whether they should be recontextualized by returning to Athens in order to be displayed in the New Acropolis Museum.

Pathological Conditions and Anomalies in Forensic Contexts

Conrado Rodríguez-Martín
Instituto Canario de Bioantropología (OAMC-Cabildo de Tenerife), Santa Cruz de Tenerife, Canary Islands, Spain

Introduction

Bone pathology is a basic tool for understanding the epidemiology of archaeological populations and the natural history of different diseases. Osteopathological analysis may also be helpful in forensic cases where identification is an issue. Bone pathology may be of use in the positive identification of individuals because pathology, in general, constitutes crucial individual characteristics (Maples 1984; Rodríguez-Martín et al. 2005). In exceptional cases, some pathological conditions can be the only guide to identification (Rogers 1987).

Stewart (1958) was one of the first to introduce the forensic implications of skeletal pathology (degenerative disease) to diagnose age and Reichs (1986a, b) to diagnose sex and ancestry. Other studies have contributed to expand the field: some diseases cause alterations in the personal appearance that can help in identifying a person (Pickering and Bachman 1997). Comparison between lesions observed in the osseous tissue and antemortem radiographs or medical records may also be extremely useful (Krogman and Iscan 1986). When examining and interpreting bony changes, it is important to consider differential diagnoses: similar bony changes can be produced by different agents. Alternatively, similar events may produce different conditions in different persons or at different time of their lives (Ubelaker 1989; Burns 1999).

While bone pathology is widely studied, it is important to note that the majority of diseases do not affect the skeleton: most diseases need a long time to develop (chronicity), and very few are a direct cause of death. The study of skeletal lesions is widely based on macroscopic analysis, but certain cases need other diagnostic methods (radiography, computed tomography, microscopy, chemical analysis, or DNA).

Examples

Metabolic Disturbances

Scurvy (Deficiency of Vitamin C or Ascorbic Acid)

Ascorbic acid is required for collagen synthesis. Therefore, a deficit may lead to subperiosteal hemorrhage (the most important sign) causing hematoma that is calcified, separation of the epiphyses, osteoporosis, and joint disturbances by hemorrhage. Scurvy is typically classified in two types: infantile, showing most of the skeletal changes, and adult showing mostly osteopenia (lower bone mineral density).

Rickets and Osteomalacia (Deficiency of Vitamin D)

A deficit of vitamin D can be produced by a failure of its intake or a renal failure leading to mineralization alterations. If this occurs in subadults, it is called rickets and in adults osteomalacia.

The condition of rickets shows widespread skeletal deformities: cranial thinning and softening with bulging fontanels; rachitic rosary; enlargement of wrists, knees, and ankles, by widening of the epiphyses; marked curvature of the long bones; and spinal kyphosis, scoliosis, and increased lumbar lordosis which contribute to decreased stature.

Osteomalacia can be the consequence of rickets perpetuated into adulthood, but it is mostly acquired (Aufderheide and Rodríguez-Martín 1998). Most individuals do not show skeletal deformities, only osteopenia.

Osteoporosis

Osteoporosis is said to be present when there is loss of 30% or more of bone mass. There are different types of osteoporosis: infantile–juvenile, traumatic, post-pregnancy, and aging-related (postmenopausal (55 years, rapid, 6 times more frequent in females) and senile (>70 years, slow, females twice affected)). The typical changes in

osteoporosis are thinning of cortical bone, generalized rarefaction of the skeleton, and compression (codfish vertebra) and pathological fractures.

Joint Diseases

Degenerative Joint Disease (DJD) (Osteoarthritis)

DJD involves diarthrodial joints. When spinal bodies (not diarthrodial joints) are affected, the condition is known as spondylosis. DJD may be acquired (e.g., through trauma or strong physical activity) and age-related (usually generalized). The most prominent features are osteophyte formation at the joint margins, increased porosity and formation of subchondral cysts on the joint surface, and later eburnation and deformity of the whole joint. Spondylosis also shows vertical disk hernia (Schmorl's nodes).

Rheumatoid Arthritis (RA)

RA is a chronic, inflammatory, systemic, and nonsuppurative disease of the synovial joints and connective tissue that causes the ultimate destruction of the joint. A probable autoimmune nature is suspected. Females are two to three times more affected than males, and its onset typically commences between the fourth and sixth decades. Hands and feet are commonly involved. The changes are polyarticular, bilateral, and symmetrical involvement of the joints; *pannus* (inflamed synovium) formation producing marginal erosions and destruction of the joints; and little, if any, reparative activity. No osteosclerosis is detected in the radiographs. The consequences are subluxation and dislocation of the joints.

Ankylosing Spondylitis (Bechterew or Marie-Strümpell Disease)

Ankylosing spondylitis is a chronic, inflammatory, progressive, and systemic disease linked to the antigen HLA-B-27. Males (whites and adolescent–young adults) are more affected than females. Its clinical picture consists mainly in spinal changes and disk disease, fusion of the sacroiliac joints (first sign), ossification of the anterior and posterior ligaments of the spine, and increased kyphosis and decreased lordosis (an inward curvature of a portion of the lumbar and cervical vertebral column). Peripheral joint involvement (hips, knees) is almost identical to RA (see above).

Diffuse Idiopathic Skeletal Hyperostosis (DISH) (Forestier-Rotés Querol Disease)

DISH consists of ankylosing hyperostosis of the spine due to ossification of the anterior longitudinal ligaments without inflammatory changes. The disk is not involved. Older males are predominantly affected.

Gout

This disease is an inflammatory arthritis, usually monoarticular, by chalky deposits (urate) due to primary or secondary (most common) hyperuricemia. Gout typically presents in the periphery of the joint causing erosions that create a punched out appearance. Reactive sclerosis is observed and osteoporosis is not present. It is more common in adult males.

Hematological Disorders

Iron Deficiency Anemia

This condition can be produced by one of the following causes: decreased intake, blood loss, or bad absorption of iron. Women are more affected.

Sickle Cell Anemia

Alterations in the B-hemoglobin chains produce deformed red cells that lead to increased hemolysis with ultimate bone marrow hyperplasia. The typical changes are osteopenia (by increased bone marrow) and then osteoporosis responsible for vertebral collapse and kyphoscoliosis, bone infarction (femoral head and spine) (Steinbock 1976), and possible osteomyelitis (mostly by salmonella).

Thalassemia

Thalassemia is produced by alterations in hemoglobin chains. It may be *major* (homozygous) and *minor* (heterozygous, with lesser bone alterations). Thalassemia is most prevalent in individuals from the Mediterranean. There is great and severe anemia with big marrow hyperplasia

causing severe osteoporosis in the skull ("hair-on-end"), appendicular skeleton ("honey comb"), and axial skeleton (kyphoscoliosis).

Porotic Hyperostosis and Cribra Orbitalia

Most types of anemia show skeletal changes in subadults, especially on the cranial vault (porotic hyperostosis) or orbits (*cribra orbitalia*). Porotic hyperostosis is characterized by lytic lesions, symmetrically distributed, in the parietals and frontal bones and in lesser degree in the occipital, showing thickening with porosity of the overlying outer table that exposes the diploe. *Cribra orbitalia* shows a similar pattern.

Multiple Myeloma (Kahler's Disease)

This is an aggressive plasma cell dyscrasia affecting persons >50 years of age. The disease is usually located in the spine and associated with possible pathological fractures; the skull and pelvis may show round lytic defects without sclerotic reaction, and more rarely osteopenia.

Infections: Nonspecific Bacterial Infections

The skeletal changes produced by nonspecific bacteria are indistinguishable.

Osteomyelitis (OM)

OM is an inflammation of bone and marrow. It is important to note that 30% of acute OM (hematogenous or by direct infection) become chronic.

Hematogenous OM

Hematogenous OM predominantly affects children (>3 years old). It is uncommon at other ages but can affect adults with chronic diseases, debilitated elders, or drug addicts. *S. aureus* is the usual germen responsible. Defects are usually located in the distal femur, proximal tibia, proximal femur, or distal radius.

Direct Infection

Puncture wounds, accidents, and iatrogenic infection are the most common causes of direct infection. It is usually polybacterial and typically involves the tibia and femur. The infection produces a defective blood supply leading to bone necrosis (*sequestrum*) that is surrounded by a shell of new bone (*involucrum*). Cloacae are also present to drain pus and detritus.

Infections: Specific Bacterial Infections

The changes produced by every bacterium are specific.

Tuberculosis

Mycobacterium tuberculosis (Koch bacillus) is the responsible bacteria. Approximately 1% of cases of tuberculosis observed in developing countries show skeletal changes. Tuberculosis affects persons of <25 years of age. The skeletal changes are produced by metastatic spread or continuity and affect the spine (vertebral collapse causes severe kyphosis or Pott's disease) and knee in children, and knee and hip in adults. Other changes include osteoporosis; marginal erosions; destruction of subchondral bone, with little bone reaction; and bony ankylosis of the sacroiliac joint (Ortner and Putschar 1985).

Leprosy

Leprosy is caused by *Mycobacterium leprae* (Hansen bacillus). It may be tuberculoid (TT), showing more skeletal changes, and lepromatous (LL). While there is evidence of leprosy in antiquity worldwide, today it predominantly occurs in tropical areas. Skeletal changes are due to direct extension more than hematogenous spread. Skeletal alterations include rhinomaxillary syndrome (*Facies leprosa*) showing erosion of the nasal margins with destruction of the maxillary area and the nasal spine along with nummular palatal perforation and loss of the upper central incisors; periostitis of the long bones; and changes due to peripheral neuropathy and anesthesia (trauma creates an infection – OM and septic arthritis – with bone destruction and marked periostitis) (Charcot's joint).

Treponematosis

It is very difficult to perform a diagnosis of each of the treponematosis without knowing the origin of the sample.

Yaws or Frambesia

Yaws or frambesia is a nonvenereal disease caused by *Treponema pertenue*. Geographically,

the disease has been observed in Africa, Latin America, Southeastern Asia, and Southern Pacific. Only 1–2% of the cases show skeletal changes: dactylitis of the hands, saber shin tibia or boomerang leg, gummatous OM of long bones without prominent periostitis, gangosa (extensive destruction of the nasal area), Goundou or "big nose" in children, and uncommon joint involvement. Spontaneous healing is usual.

Bejel, Nonvenereal Syphilis, or Endemic Syphilis

Nonvenereal and caused by *Treponema pallidum endemicum*, it is an acute children's disease of the Eastern Mediterranean and Southwestern Asia. 1–5% show skeletal changes: saber shin tibia, gummatous destruction, and nasal–palatal destruction similar to gangosa. Spontaneous healing is usual.

Venereal Syphilis

Venereal syphilis is caused by *Treponema pallidum* pallidum and may be acute, subacute, and chronic. It predominantly affects young people and occurs worldwide. The skeletal lesions include gummatous lesions that appear in advanced stages involving skull (parietal, frontal, and nasal–palatal involvement) and tibia showing the pattern of the skull (thickened cortex and rough surface). Although less frequently, other bones are also involved. Gummatous arthritis is rare.

Nongummatous lesions show periostitis, especially at the metaphysis, leading to cortical thickening and deformation causing narrowing of the medullary cavity and saber shin tibia.

Neurosyphilis: Charcot's joint in large joints.

Congenital Syphilis

Congenital syphilis is caused by *Treponema pallidum pallidum*. There are two types: early or infantile showing osteochondritis at the epiphysis and metaphysis plus diaphyseal osteitis and periostitis, and late with gummatous and nongummatous OM or periostitis with diffuse hyperostosis, dactylitis, and Clutton's joints (more in knee and bilateral) and teeth anomalies (Hutchinson's teeth and Moon's molars).

Congenital Malformations: Cranial Malformations

Craniosynostosis

Craniosynostoses are the most common form of cranial malformations and are the result of the earlier closure of a cranial suture. The most clinically significant are scaphocephaly (sagittal suture closure causing hyperdolicocephaly), plagiocephaly (asymmetrical suture closure), turricephaly (coronal suture producing a tower-shaped skull), trigonocephaly (metopic suture giving a triangle-shaped skull), and triphyllocephaly (multiple closure resulting in a trilobular skull).

Congenital Malformations: Spinal Malformations

Atlas Assimilation

Atlas assimilation refers to the partial or total fusion between the atlas and the skull base. One percent of the population is affected, and around 50% show C2–C3 fusion.

Spina Bifida

Spina bifida is the most common of all spinal malformations, consisting of incomplete bony closure of the neural arches, especially at the sacrum. It may be aperta (very severe condition in which meninges are not protected by skin, muscle, or bone) or occulta (the most common form).

Transitional Vertebrae at the Lumbosacral Level

There are two types: sacralization of L5 (the sacrum appears with six segments) and lumbarization of S1 (the sacrum shows four segments only). Both can be complete or partial.

Vertebral Block

Vertebral block refers to the fusion of two, three, or more vertebrae in a block that may involve spinous and transverse processes.

Spondylolysis and Spondylolisthesis

This is a failure of ossification in the pars interauricularis producing separation of the vertebra in two parts, one anterior and other posterior,

that can be displaced (spondylolisthesis). Minor trauma plays an important role in its origin.

Thoracic Malformations

Cervical Ribs

It is an elongation of the transverse process of C7 becoming a rib with head, neck, and body but very rarely reaches the sternum.

Pelvic Malformations

Congenital Dislocation of the Hip

This condition is based on the loss of the normal relationship between the femoral head and the acetabulum. If not treated, the result is a dysplastic acetabulum, deformed and flattened head, and formation of a false acetabulum (neoacetabulum). It seems to be hereditary, and there are examples of familial cases. In general, there is a considerable population variation. Frequency: 1 to 15–20 per 1000 of live births worldwide (Aufderheide and Rodríguez Martín 1998). 25–50% of the cases are bilateral, being the left side more affected in the rest. Females are more affected than males (5–8: 1).

Limb Malformations

Upper Limb Anomalies

Madelung's deformity Seventy percent of the cases show bilateral involvement with shortening and bowing of the distal radial third that due to the difference in length with the ulna leads to congenital subluxation of the wrist.

Carpal Blocks This is a relatively uncommon diseases characterized by fusion of two or more carpal bones.

Lower Limb Anomalies

Developmental Coxa Vara Both sexes are equally affected. The changes are short femoral neck and an angle of less than 120°, osteoporotic head and elevated greater trochanter producing short limb (>5 cm), and degenerative joint disease in adulthood.

Tarsal Blocks The most common are talocalcaneal, calcaneonavicular, and talonavicular coalition.

Skeletal Deformities

Scoliosis

This anomaly is based in the lateral curvature of the spine with rotation of the vertebrae and spinous processes toward the concavity where the ribs are approximated among them, being pedicles and laminae thinner and shorter than normal. There is a cuneiform aspect of the vertebra. Several types are observed: the idiopathic type is the most common (80%) appearing at 10–12 years and being inherited and familial (30% of the cases), followed by the paralytic type that is commonly located at the thoracic–lumbar level. The less frequent type is the secondary to localized spinal malformations.

Bone Tumors

A tumor is a cellular proliferation without the control of normal growth-regulating mechanism. Benign tumors show limited growth potential, meanwhile malignant neoplasms manifest much greater growth autonomy and this leads to invasion of other organs.

Benign Bone Tumors

Osseous Origin Button osteomata are solitary, slow-growing tumors of compact bone, usually involving the cranial vault but may involve sinuses and orbit. Adult males are more affected.

Ossifying fibroma typically affects adolescents and young adults. Jaws and, uncommonly, diaphyses and metaphyses of long bones (tibia, showing anterior bowing) are the most involved bones (the epiphyses are spared). Osteolysis and cortical thinning and expansion are the typical features (Aufderheide and Rodríguez-Martín 1998).

Osteoid osteomata affect children and adolescents and are relatively common. Males are twice as likely to be affected. Osteoid osteomata tend to be small and have solitary foci involving the end of diaphyses of the bones of the lower limb, within the cortex, showing peripheral sclerosis.

Vascular Origin Hemangiomas are tumors that affect middle-aged individuals and involve the vertebrae and the skull. The lesions are cystic cavities showing thickened vertical trabeculae.

Fibrous Origin Nonossifying fibroma (fibrous cortical defect) affects children. The skeletal changes include a solitary, eccentric, and well-demarcated lesion at the metaphysis of the femur and tibia which produce cortical erosion with sclerotic margins. Pathological fractures can occur.

Cartilage Origin Osteochondroma (exostosis). This lesion accounts for almost half of all benign bone tumors, affecting individual under 30 years. It is usually located on metaphyses of the lower femur and upper tibia, as a projection of the bone surface with a core of trabecular bone continues with that of the metaphysis and covered by normal cortex. The size varies and the shape may be sessile or pedunculated.

Enchondromas are common tumors involving short bones as an intramedullary lytic lesion. Although the cortex is usually spared, pathological fractures can occur.

Miscellaneous Tumors

Giant cell tumor appears in the third to fourth decades like a locally aggressive lesion (lytic and eccentric, without sclerosis), located at the epiphyseal end and at the metaphyses of long bones.

Primary Malignant Tumors

Osseous Origin Osteosarcomas (osteogenic sarcomas) are the most common primary neoplasm of bone (20% of all bone tumors) and affect children, adolescents, and young adults (mostly males). 50% are osteoblastic, being central or parosteal (periosteal and intracortical are very rare), and the metaphyses are usually affected. The common pathological findings are "sunburst" pattern, Codman's triangle, and certain degree of sclerosis.

Cartilage Origin Chondrosarcomas are the second most common malignant primary tumor of bone and involve the medullary cavity of the femur and tibia at the metaphysis showing defects with scalloped and poorly defined inner cortex. Adults are most commonly affected.

Metastatic Tumors

Most malignant skeletal lesions are metastases, appearing in individuals over 40–50 years. The most metastasizing are prostatic carcinoma and breast carcinoma, and the most involved bones are vertebrae, pelvis, ribs, major limb bones, sternum, and skull. The lesions are usually osteolytic, while most prostatic metastases are osteoblastic.

Circulatory Disturbances of Bone

Osteochondritis Dissecans (König Disease)

This condition affects males more than females, at 10–25 years. Its etiology is not completely known (idiopathic, vascular factor, trauma). It is a benign, noninflammatory condition of the diarthrodial joints (especially femoral condyle, talus, and elbow), showing foci of skeletal necrosis being the cartilage spared. The typical feature is a craterlike lesion which may range from several millimeters to centimeters in size. The lesions are most commonly unilateral and sporadic although familial cases have been observed (probably CE).

Osteochondrosis

Osteochondrosis affects individuals of less than 10 years, mainly males. The etiology is varied (trauma, steroid therapy, idiopathic). It is a benign and noninflammatory condition of the apophysis and epiphysis. Multiple involvements may occur. The typical lesion shows increased bone density at the beginning and then subchondral radiolucency leading to the collapse of the articular surface and joint fragmentation producing joint deformity.

Patterson, Thomas Carl

Wendy Ashmore
Department of Anthropology, University of California, Riverside, CA, USA

Basic Biographical Information

Anthropologist, social theorist, and activist-critic, Thomas Carl Patterson was born on November 5, 1937, in Rutland, Vermont. He received his B.A. in Anthropology from the University of California, Riverside (1960), and his Ph.D. in Anthropology from the University of California, Berkeley (1964). He held teaching positions at Berkeley, briefly, and then at Harvard, Yale, and Temple Universities before joining the faculty at the University of California, Riverside, in 2000. During field research in Peru in the 1960s, civil unrest paralleling events at home in the United States led him to question mainstream approaches to understanding social order and change. Reading Marx opened what Patterson found more effective lines of thinking, and since then, his writings and activism have reflected his commitment to social justice, informed by a profoundly Marxist perspective. A critical autobiographical statement (Patterson 2003: vii–xvi) gives a fuller account, complemented by a thoughtful perspective from Latin America (Tantaleán 2011).

Major Accomplishments

Patterson's initial research addressed socioeconomic, demographic, and environmental topics in ancient South America, drawing on settlement patterns, pottery, and stone tools as primary evidence (1971). In the first decade of his career, publications ranged widely in context, from earliest human occupation through Inca times, and across Andean South America's coast and highlands. His analytic and reporting skills emerged in his earliest publications, including his dissertation on the Miramar and Lima pottery styles of Peru's central coast (1966); analyses reported therein are

fundamental reference points today. His research is so solid that, in 1971, for the South America volume of a landmark synthesis of American archaeology, Gordon R. Willey cited Patterson's unpublished, preoral reviews of South American research as key sources.

Patterson's methods and interpretations fit comfortably in archaeological frames of the time, showing little yet of the theoretical and political transformations he was experiencing. Through the late 1970s, Patterson worked out his new ways of thinking largely in teaching, not publications (personal communication). Classroom settings have often inspired his subsequent writing, in textbooks and other venues (1983b, 1997a). His attentive mentoring has boosted countless students and colleagues, including the 30-plus whose dissertations he has supervised through 2010.

By the early 1980s, transformations in his thinking were rendered firmly in print. He openly challenged positivist, ahistorical approaches to past societies, arguing that historical materialism yielded deeper, more compelling insights about people's lives. This standpoint was first explicit in writings on class and state formation in Peru (1983a), interpretations that coalesced in his book on *The Inca Empire* (1991), and a cross-cultural, edited volume of concepts, processes, and case studies (Patterson and Gailey 1987). He has since pursued such analysis in other settings as well (1997b).

Also in the 1980s, Patterson embarked on critical social histories of theory and practices in archaeology and anthropology, especially in the USA and Latin America (1989). His work in this domain accelerated in subsequent decades (1994, 2001), especially as he wrote more about social inequalities of race, class, gender, and other forms of social diversity (Patterson and Spencer 1994; Patterson 1995, 1997a; Susser and Patterson 2001). He remains deeply concerned with the intersection of such unequal positions and the politics in which they are embedded, including challenges to free speech and academic freedom, and the politics of knowledge production. He has been active in civil rights and antiwar demonstrations at home, solidarity with oppressed peoples abroad, and labor unions, supporting strikes and rights to organize. Patterson participated as well in actions giving rise in 1986 to a newly independent World Archaeological Congress (WAC), the aftermath of conflicts over including South African scholars and protesting apartheid. Theory and praxis are inseparable for him.

Patterson has continued critical consideration of theoretical trends in archaeology, placing in historical contexts the provisions of and tensions among such perspectives as processualism, post-processualism, and postcolonialism (2008a). He frequently critiques archaeologists' failure to recognize the widespread political and economic change wrought by capitalism and their use of interpretive models based in capitalist experience to interpret pre- or noncapitalist situations (2008b). In counterpoint, he applauds the union of theory and praxis in Latin American social archaeology (1994; Tantaleán 2011) and other expressions of social engagement, including Indigenous, feminist, and Marxist archaeologies.

As a social theorist, Patterson seeks to articulate archaeology more firmly with history, economics, and other social scientific and humanistic disciplines, beyond its home in the USA within anthropology (2008b). He also believes firmly in an integrated anthropology, of which archaeology is only one part. At the same time, he advocates and embodies moving beyond one's country, culture, and language of origin, connecting with diverse scholars and intellectual traditions. Increasingly his attention overtly encompasses explanations for social order and change today, expanding on early concerns for historical inclusiveness; *Change and Development in the Twentieth Century* (1999), for example, evaluates perspectives on this very recent period based in works of Weber, Durkheim, and Marx.

Combining social theory, archaeology, and his historical sensibilities, Patterson has turned to examining intellectual biographies of scholars he views as fundamental contributors. He began with Marx, with whose ghost whom Patterson (2003) contended archaeologists hold continuing conversations. In 2004, Patterson and Charles Orser reproduced select writings of V. Gordon Childe,

who, as a scholar-activist, intellectual, and Marxist, became "one of the most eminent archaeologists in the twentieth century" (p. 1).

Fittingly, Patterson (2009) returned to Karl Marx, assessing what the latter thought about nascent anthropological ideas and findings and what his legacies to today's discipline are. Archaeology takes backstage in this book, but from the preface on, it reveals much about Patterson and the integration of his archaeological and anthropological thinking.

In research, teaching, and publication, Patterson keeps expanding themes established at varied points in his career. He works on projects as varied as race and the history of anthropology, class conflict and state formation in archaeology contexts, and from the deep past to the present, changing political economy in southern California's Inland Empire. He continues confronting inequities, through practices in archaeology, anthropology, and daily life. His is truly a life unified in theory and praxis.

Peabody Museum of Archaeology and Ethnology (Harvard University)

Katharine Vickers Kirakosian
Department of Anthropology, University of Massachusetts Amherst, Amherst, MA, USA

Introduction

The Peabody Museum of Archaeology and Ethnology is one of the oldest anthropology museums in the world and the oldest anthropology museum in the United States. It is located in Boston, Massachusetts, and was founded on October 6, 1866, after philanthropist George Peabody gave a modest gift of $150,000 to Harvard University in support of a museum and a professorship of American archaeology and ethnology (Putnam 1898). Peabody was inspired to do this after his nephew, soon to be Yale Professor of Paleontology O. C. Marsh, approached him in 1865 about his avocational interests in the nascent field of American archaeology (Putnam 1898).

The museum holds around 10 million items. About 2.5 million items, roughly one quarter of the museum's collection, are from North America (Peabody Museum of Archaeology and Ethnology 2013). Perhaps one of the most celebrated parts of the North American materials is the largest surviving collection of objects from the Lewis and Clark expedition. The museum's Central American collections include an impressive array of Mayan and Aztec artifacts and monument casts. The South American collection contains items from the Amazon basin, Bolivia, and Peru, including an impressive array of Peruvian textiles and quipus. (Peabody Museum of Archaeology and Ethnology 2013). This collection also includes materials from Asia, Africa, Oceania, and Europe. The museum's archives are also rich and include 500,000 historical photographs, hundreds of paintings and drawings, and numerous research records. Today, much of the Peabody Museum's collection can be accessed and viewed online.

Key Issues

The museum's first curator was Dr. Jeffries Wyman, who graduated from Harvard College in 1833 and Harvard Medical School in 1837, and was appointed as curator in 1866. Wyman, who had also served as the Hersey Professor of Anatomy at Harvard College since 1847, held both positions until his death in 1874. As the first curator, Wyman worked diligently to grow the museum's collections, which had grown to some 8000 items by the time of his death (Browman 2002). He accepted donations from scholars and colleagues, including Harvard University's Louis Agassiz, Alexander Agassiz, and Henry David Thoreau. Wyman also purchased thousands of artifacts from Europe and led several expeditions throughout Maine, Massachusetts, and Florida to collect his own specimens as well (Browman 2002). These first collections were initially assembled in Wyman's laboratory in Harvard's Boylston Hall and then in the Anatomical Museum, until construction of the Peabody Museum was completed in 1878.

Frederic Ward Putnam, a former student of Wyman's and Agassiz's, was appointed the second curator shortly after Wyman's death and a brief interim curatorship by Asa Gray. Putnam held this position from 1874 until 1909. Called the father of American archaeology by his contemporaries, Putnam worked to establish the Peabody Museum as more broadly focused on archaeology, physical anthropology, and ethnology (Browman 2002). Under Putnam's guidance, Ohio's Serpent Mound was purchased and Serpent Mound Park was established (Putnam 1898). It was not until 1886 that the professorship was actually established, which was filled initially by Putnam (Putnam 1898). Less than a decade later, Putnam helped create a series of exhibits for the

1893 World's Colombian Exposition in Chicago, where Franz Boas served as one of his assistants. Under Putnam's guidance, the artifact collections and library holdings expanded at such a fast rate that by 1889 an addition was built that more than doubled the museum's square footage. Immediately prior to the close of the century in 1897, the Peabody Museum officially merged with Harvard University.

Frederic Putnam facilitated the establishment of the Peabody Museum Press in 1888, which continues to publish monographs, reports, and other papers (Peabody Museum of Archaeology and Ethnology 2013). These include the *Papers of the Peabody Museum of Archaeology and Ethnology*, which has highlighted many of the 800 expeditions that the museum has supported across the globe (Spencer 1997). Through the Peabody Museum and their Central American Expedition Fund, some of the earliest research was conducted on sites such as Copan (1891–1900), Seibal (1895), and Chichén Itzá (1904–1910). Gordon Willey, who joined the Peabody Museum in 1950, continued to explore some of these earlier sites in the Yucatan.

The museum's first ethnological expedition took place in Peru and Bolivia between 1906 and 1909, led by William Curtis Farabee. Decades later the museum supported John Marshall's ethnographic research in the Kalahari Desert from 1950 to 1961 (Peabody Museum of Archaeology and Ethnology 2013). This research inspired John Marshall and Robert Gardner to found the Harvard Film Studies Center through the Peabody Museum in 1957. Some of the earliest ethnographic films produced here include classics like John Marshall's *The Hunters* (1957) and Robert Gardner's *Dead Birds* (1963).

Current Debates

After the 1990 passage of the Native American Graves Protection and Repatriation Act (NAGPRA), the Peabody Museum founded a repatriation office that has been working to repatriate human remains, funerary objects, sacred objects, and objects of cultural patrimony. This has been an ongoing task, considering that the museum's collection included roughly 22,000 sets of human remains (Bethell et al. 2004). Not all remains fall under the jurisdiction of NAGPRA, as the Peabody Museum's osteological collection originates from more than eighty countries and six continents (Peabody Museum of Archaeology and Ethnography 2013).

The Peabody Museum currently supports three research labs: the Gordon R. Willey Laboratory for Mesoamerican Studies, the Paleoanthropology Lab, and the Zooarchaeology Lab (Peabody Museum of Archaeology and Ethnology 2013). Current projects include a 3D scanning project on Mayan monuments (started in 2007), the Corpus of Maya Hieroglyphic Inscriptions Program (started in 1968), the Harvard Yard Archaeology Project (started in 2005), and excavations at Magdalena de Cao Viejo (started in 2004) (Peabody Museum of Archaeology and Ethnology 2013). In 2012, the Peabody Museum became part of the Harvard Museums of Science and Culture consortium, which includes six other Harvard University museums.

Peach: Origins and Development

Alison Weisskopf and Dorian Q. Fuller
Institute of Archaeology, University College London, London, UK

Basic Species Information

Peaches (including nectarines), *Prunus persica* (L.) Batsch. syn (*Amygdalus persica* L.), are the edible fruit of a deciduous tree belonging to the subfamily Prunoideae (family Rosaceae), which also includes apricots, cherries, plums, and almonds. Some taxonomists maintain peaches and almonds are very closely related within the genus *Amygdalus*. The name peach derives from the Greek *Persikon malon* for "Persian apple" into Latin *malum Persicum*, which became *pêche* in French and peach in Middle English. Although first cultivated in China, the name *persica* stems from the pre-nineteenth-century European belief that this tree originated in Persia (Bassi and Monet 2008). Nectarines are smooth-skinned hairless varieties of peach (*Prunus persica* (L.) Batsch var. *nucipersica* (Suckow) C. K. Schneid.), and they might have originated more than once as a mutant within peach groves. Nectarine stones are indistinguishable from other peaches, meaning that archaeobotanically their origins cannot be traced, but some early written sources have been interpreted as indicating the presence of nectarines as early as 2,000 years ago in the Mediterranean.

Major Domestication Traits

Wild forms of peach grow in central and eastern Asia and these are interfertile with cultivars (Zohary et al. 2012). Self-compatibility seems associated with cultivation. All related species are self-incompatible (Ladizinsky 1998), while under cultivation selfing assures higher fruit production rates. It is likely that the peach arrived in the Mediterranean, represented in Greek texts from Persia before 300 BCE (Zohary et al. 2012), having spread from Central Asia and northwest India earlier still. Peaches were then spread more widely in Europe by the Roman army.

The earliest diploid *Prunus* probably arose in Central Asia splitting into the ancestral species of *P. persica*, which then evolved in north and northwest China (Bassi and Monet 2008). True wild peaches are generally regarded as native to northern China (Lu and Bartholomew 2003), but the progenitor populations of cultivars may be extinct given the massive anthropogenic transformation of the Chinese landscape. Some authorities point to *Prunus davidiana* (Carr.) as the closest wild relative (e.g., Scorza and Okie 1990), and this species is prominent in breeding research to improve peaches. *P. davidiana* occurs in middle elevation thickets throughout the hills of northern, western, and southwestern China (Lu and Bartholomew 2003). Wild peaches *P. persica* are also reported as "escapees" from cultivation especially in northwest China.

There is vast diversity within the modern cultivars (Bassi and Monet 2008). Most peach subspecies have a chilling requirement of between 600 and 1,000 h and require heat to mature the crop so their range is limited to warm temperate, continental regions, or high altitudes. They are found just above 3,000 m in parts of the Himalayas. The trees can tolerate low temperatures (to −30 °C) but the buds and flowers are susceptible to frost.

The fruit is a drupe with a soft mesocarp and pubescent, velvety (peach), or smooth (nectarine) exocarp. The endocarp is lignified and corrugated with deep furrows and pits on the outer surface (Fig. 1). The patterning on this, including deep double groves near the suture of the endocarp's two halves, allows relatively small fragments to be identified. There is a pronounced ridge along the ventral suture and sometimes a very acute tip at the apex. Inside this hard shell is the starchy kernel. The seed can contain high levels of hydrogen cyanide. Nevertheless, with detoxification it is likely that these kernels were food resources in parts of Neolithic China (Hosoya et al. 2010).

Peach: Origins and Development, Fig. 1 At the *left* is a drawing of a peach endocarp, showing the distinctive longitudinal furrows. (After Darwin 1868), at the *right* is a photograph of a Neolithic waterlogged peach stone (*P. persica/davidiana* type from Tianluoshan, Zhejiang (6500–7000 BP)) (Photo by DQ Fuller)

Timing and Tracking Domestication

While there has been documentary evidence for peach cultivation in China for over 3,000 years (Bassi and Monet 2008), archaeological evidence is even earlier. Determining, however, when wild gathering turned to propagation remains a challenge. Sites in the middle and lower Yangtze regions (extending back to 7000–8000 BP) have peach stone finds (of either *P. persica* or *P. davidiana*), such as Bashidang, Hunan (7000–6000 BP); Chengtoushan, Hunan (4500–4000 BCE); Kuahuqiao, Zhejiang (6000–5400 BCE); and Hemudu and Tianluoshan, Zhejiang (4900–4600 BCE) (Table 1 Hosoya et al. 2010). Peaches also occur in central China, along the Yellow River region from the Yangshao period onwards (about 6000 BP), but with more frequency from c. 5000 BP. It may be that systematic cultivation only began at this time. However, reports of peach from a Jomon site in Japan (Kiriki, Nagasaki) dating to 5500–6000 BP (D'Andrea 2007) could point to an earlier period of propagation and translocation.

There can be no doubt that by 4000 BP peaches were cultivated, as it is around this time that they are first introduced to northwest India. Here, they are reported from late Neolithic Kashmir and together with apricots can be attributed to a "Chinese horizon" of crops introduced via Central Asia at this period (Boivin et al. 2012).

The introduction further west into Persia remains to be better documented, but classic written sources from the fourth century imply that it was already well established there. In the Mediterranean the earliest finds are from the seventh-century BCE Heraion, Samos (Zohary et al. 2012). By the first century BCE, Romans were cultivating peaches in southern Europe, Israel, and Egypt. During the Roman period Pliny (CE 79) describes how the peach had recently been imported into Europe from Persia and Egypt from Rhodes (Bassi and Monet 2008). Peach is recorded at 32 Roman period sites in Europe, most in the south. The northern sites are military settlements so it is likely any peaches were imports (Bakels and Jacomet 2003). A second route to Europe could have been via the Black Sea and Danube. By the Middle Ages France had become a major producer and the peach reached the Americas by the first half of the sixteenth century (Bassi and Monet 2008). The earliest mention of nectarine varieties is in the fourteenth century CE.

Introduction

The peopling of America is still one of the most controversial issues of world prehistory, regarding its chronology, number and routes of population waves, and palaeoanthropology. As well as some other case studies, the "question" is the result of (seldom undeclared) contentions in different domains, such as methodological perspectives, intrinsic data limitations and – finally – academic traditions and relationships. From 1927 onward, when the discovery at Folsom (New Mexico, USA) of a lithic spearpoint plunged into the ribs of an extinct bison symbolically launched the acceptance of Paleo-Indian peopling of North America, many sites have been proposed as much older than the limit between Pleistocene and Holocene, conventionally fixed at 12 ky BP. Few of them, nevertheless, have survived careful revision and screening of their evidence, for chronological, taphonomic or strictly archaeological reasons (Dillehay and Meltzer 1991; Dillehay 2010).

Definition

Pedra Furada (the abbreviation of Toca do Boqueirão da Pedra Furada) is a sandstone rockshelter in the southeastern portion of Piaui state, North-Eastern Brazil (8°50′ 09" South, 42°33′20 West), 30 km northeast of the town of São Raimundo Nonato (Fig. 1). The relevance of the site is due to its very old dates, spanning from 5 to at least 60 ky BP for a sequence of occupation layers and stone tools, and to the consequent debate issued about the chronology of first peopling of the Americas. The site is very well dated by a coherent radiocarbon sequence, but it did not provide human fossil remains, so the burden of proof of the consistence of the human presence leans entirely on the cultural origin of archaeological structures, hearths and lithic industries, just the matter of contention. The site has been excavated first by Niéde Guidon between 1978 and 1987, and then by Fabio Parenti from 1987 to 1988 (ongoing report in Guidon and Delibrias 1986; Delibrias et al. 1988; Parenti et al. 1990; Bahn 1993), and entirely published by the latter (Parenti 2001); new researches are still (2012) underway by a French–Brazilian team led by Eric Boeda.

Historical Background

Pedra Furada, as well as many important sites in South-Eastern Piaui, was discovered in the seventies by a French–Brazilian team led by Niéde Guidon, a former student of André Leroi-Gourhan, sponsor of the *Serra da Capivara* National Park (http://www.brasil.gov.br/localizacao/

Pedra Furada, Archaeology of, Fig. 1 Aerial view of *Baixão* da Pedra Furada, looking North. The canyon is entailed in the Devonian *Serra Grande* formation. *White arrow* pointing to shelter. The total height of *cuesta* is about 150 m. (Modified from Parenti 2001)

parques-nacionais-e-reservas-ambientais/parque-nacional-serra-da-capivara-pi%20) and responsible from 1987 onward for the *Fundação Museu do Homem Americano*, an important international resea rch center in São Raimundo Nonato (www.fumdham.org). The team was, at that time, surveying the a rea of the Siluro-Devonian sandstone *cuesta* of southern Piaui, where many painted shelters had been signaled by local authorities. Some of them were tested, in search for a firm chronology of figurative and geometric prehistoric paintings and engravings, so richly diffused in brazilian *Planalto*, Amazon and *Nordeste* regions. Pedra Furada itself was first tested in 1978 and 1980, obtaining surprisingly old (final Pleistocene) radiocarbon dates from charcoal and *cuvette* fireplaces. Regular excavations took place in 1982, 1984, 1985, and 1987 in the western portion of the shelter (grossly 30% of the whole filling), under the direction of Niéde Guidon, a nd from 1987 to 1988, Fabio Parenti led excavations on the remaining 60% of the eastern side.

During the 10 years of excavation process at Pedra Furada, some important changes took place, both in American prehistory itself, such as the research in Monte Verde (Chile) (Meltzer et al. 1997) and the contention on some "robust" Pre-Clovis sites as Meadowcroft (USA), and in methodological and technical terms: a more generalized adoption of middle-range strategy in South American archaeology and the diffusion of thermoluminescence (TL) and accelerator-mass-spectrometry (AMS) dating. For almost 10 years, Pedra Furada has been the spear point of the oldest South American sites challenging the Clovis-first model for the peopling of Americas, but today its informative potential is largely underestimated, both because of its uniqueness in South American archaeological context, but also because of the intrinsic nature of the debate on antiquity of peopling, with an exhausting succession of announcements and dismissals, and the lack of fully Pleistocenic human remains in Americas.

Key Issues/Current Debates

The sheltered area (around 700 m^2) is located at bottom of a sandstone overhang, 70 m high, composed by cross-stratified estuarine sandstone of *Serra Grande* Formation of the Piaui-

Maranhão basin. The site, facing South, is quite open to sunshine during November and December, but gently shadowed in the rest of the year, providing a remarkable standpoint at the entrance of one of main canyons of the region (*Boqueirões*), as proven by number of archaeological sites upstream (Fig. 1). The shelter is surrounded, East and West, by two waterfalls, still active today, eroding the uppermost conglomerate of the cliff (Fig. 2). The eastern waterfall, the highest, at the bottom of which there is a talus of quartz cobbles, is the main source of raw material (and geofacts)both in Pleistocene and lower Holocene times, and this is what led to the dismissal of the oldest archaeological units by many authors. The features of gravitative fracture occasionally observed on some pebbles and cobbles have been measured both on western and eastern waterfalls on a sample of 2000 stones >32 mm, and applied to the selection of purported lithic industries (details in Parenti 2001: 135–150). It resulted that the waterfalls produced no cobbles with more than three clear flake-scars >10 mm, no bifacial trimmed pieces, nor uncortical butts on pseudo-flakes.

Pedra Furada, Archaeology of, Fig. 2 Wall sections and position of waterfalls: (*1*) dripline; (*2*) unexcavated deposit (1988); (*3*) top surface interested by waterfalls; (*4*) Devonian cross-stratified sandstone of *Serra Grande* formation; (*5*) conglomerate with quartz cobbles; (*6*) conglomerate with quartz pebbles; (*7*) maximum occupied surface in *Pedra Furada* phase (Pleistocene), as defined by structures and hearths. (Modified from Parenti 2001)

The filling of the shelter, as is usual in the evolution of sandstone walls in tropical climate, has been allowed by repeated block collapses barring and protecting endogenous and anthropic sediment from erosion. The first are composed by disaggregating sand and sandstone slabs from the roof and by quartz cobbles from uppermost conglomerate layers; the last, anthropic component is made from cobbles and pebbles for stoneworking and boarding of fireplaces, selected on the talus or transported from outside, and the mineral fraction of past organic components such as plant or animal remains. Because the very acid siliceous sediment did not allowed conservation of bone remains older than 6–8 ky BP, we do know anything about Pleistocene fauna in this site, which makes correlation with opposite, fossiliferous, limestone caves (1.5 km) essential.

The whole archaeological sequence is contained in the 5 m of sediment fill, with an average East to West dip of 10° and a slight concavity in the middle (Fig. 3). The sandy and gravelous sedimentary matrix contains several charcoal lenses derived from the gentle slopewash of fireplaces, the stony boarders of which have sometimes been partially removed but mainly preserved in the uppermost eastern side.

Excavation technique from 1982 onward has been by "natural layers", i.e., simply paying careful attention to sedimentary structures and strata formation, at that time quite an innovative strategy in the context of Brazilian archaeology. A total of 2050 m^3 of sandy and gravelous sediments were removed, leaving a bulk for future research and specific analysis that was partly excavated by Boeda's team in 2010 but is still unpublished. Sediment inside the drip-line was dry-sieved (1 mm mesh) and every macroscopic remain was collected, mainly for the recovery of the overabundant charcoal fragments, both for dating and anthracological purposes. Basic sedimentological analysis was performed by Joel Pellerin (Centre National de la Recherche Scientifique, Caen, France) on the main section, and a detailed study of the remaining eastern block was conducted in 1996 by Evelyne Débard (Centre National de la Recherche Scientifique, Lyon, France), but it is still unpublished.

The chronology of the site was established on the basis of 55 (14 Holocene, 41 Pleistocene)

Pedra Furada, Archaeology of, Fig. 3 Western face of preserved block: (*1*) fine sand with ashes, charcoal and botanical macroremains (historical period); (*2*) fine sand, incised on the southern side by a channel dug in 1982; (*3*) medium sand with ashes and charcoal, with termite galleries; (*4*) medium sand with gravels; (*5*) charcoal lens in fine and medium sandy matrix; (*6*) medium sand with gravel; (*7*) charcoal lens in fine and medium sandy matrix, Southern limit is blurred; (*8*) medium sand with gravel; (*9*) sandy lens with charcoal, less than upper units, with blurred limits; (*10*) medium sand with some quartz pebbles in southern part, sandstones slabs; (*11*) bottom sandstone block collapse. *Vertical scale* refers to the whole height of the deposit. (Modified from Parenti 2001)

coherent radiocarbon dates by five different laboratories with standard 14C, AMS with acid-base-acid (ABA) and acid-base-wet (ABOX) pretreatments for samples older than 35 ky (Santos et al. 2003). The whole sequence is presented in Fig. 4. Moreover, 39 dates have been performed on heated quartz pebbles of the lowermost units of the eastern sector, yielding ages comprised between 35 and 150 ky BP (Valladas et al. 2003). The units dated both by radiocarbon and TL show an acceptable concordance, but the lowermost TL dated samples, reaching 160 ky, have been skeptically considered by the authors themselves because of possible reworking of the lower deposit or natural origin of fires. In sum, the Pedra Furada sequence is fully upper-Pleistocene and chronology is not a matter of contention per se, but the cultural content of it has been regarded as a fanciful conjecture by some colleagues (Meltzer et al. 1994), and, despite detailed reply (Parenti et al. 1996), the site is still waiting for full acceptance by archaeological literature.

Adopting the minimum duration for the total sequence (55 ky), we can roughly evaluate an average sedimentation rate of about 1 mm per 10 years, a serious challenge for any reasonable

P

attempt of reconstructing "past behaviors" or similar paleoethnological mirages in this kind of deposit, which is, at least in the Pleistocene, a cumulative palimpsest (*sensu* Bailey) of probably occasional, episodic, visits for raw material procurement, or a temporary camp for other (archaeozoologically) unknown purposes; in the Holocene, the site became a more substantial "central place" in the context of ecotone landscape of sandstone *cuesta*, as strongly indicated by structured stratified hearths, lithic complex reduction sequences and art depiction.

On the basis of radiocarbon chronology, the position and correlation of sedimentary bodies, the sequence was subdivided in six units (Fig. 4), three for the upper Pleistocene, named *Pedra Furada* (PF) 1–3 layers, two for the lower *Serra Talhada* (ST) 1–2 and one for middle Holocene *Agreste* (AG). For the Pleistocenic phase (PF), this is partly an arbitrary subdivision, because the main sedimentological and cultural traits do not show relevant changes, either in lithic tradition or regarding the general pattern of site exploitation (Fig. 5).

Archaeological features have been described and interpreted on the basis of a morphological and technical analysis of their conservation and construction. In fact, the main goal at the time of the excavation was twofold: firstly, the distinction between anthropic and natural (sedimentary) origin in the disposition of structures (i.e., arrangement of cobbles, pebbles and sandstone slabs); secondly, the identification of the agents responsible for combustion. Bush fires in tropical landscape, both semi-arid as today, or wetter as in final Pleistocene, are trivial and we cannot exclude them at all; but they usually leave homogeneous combustion traces on the uppermost soil, at fairly low temperature. Moreover, the average 10° dip of the eastern talus of Pedra Furada caused episodic scour of smaller or lighter sedimentary particles, such as charcoal. In fact, the highest density of charcoal remains was recovered in the middle, lowest, portion of the site and so the observed, apparently "unheated", upstream structures could have perfectly pertained to fireplaces. Because of these taphonomic problems, we paid special attention to the position of heated stones all over the excavations; this led to the publication of an ongoing report (Parenti et al. 1990) in which, thanks to the contribution of TL techniques, we were able to demonstrate the non-chaotic position of heated elements of some of the oldest hearths of Pedra Furada 1 layer, i.e., their anthropic origin. On this basis, the following study (Parenti 2001: 109–132) of the whole body of identified structures (156, 86 of which were in *Pedra Furada* phase) was classified mainly on physical (presence of heated elements or clearly associated charcoal or both) and morphological (form, depth, number and contiguity of elements) criteria.

For many stone features, TL samples showing no clear macroscopic evidence of fire (reddish cobbles or concentrated charcoal) were not available, so they can be arranged both in the fireplaces or simple, apparently unheated, structures categories. However, in some cases, well-defined stone circles have also been observed in *Pedra Furada* layers, such as the astonishing stone ellipse in Fig. 6, well far away from the talus slope and just close to the most protected area of the site, excluding fancy interpretation about its "natural" origins. This structure has not been directly dated because of the absence of charcoal inside, but it pertains to the PF2 layer, with an approximated age of 30 ky BP.

The spatial distribution of structures, both heated and not, shows a clear concentration in the easternmost sector, just below the best preserved painted panels of *Nordeste* (lower Holocenic) figurative "tradition". Because the resolution potential of the site is very weak (a feature of 10 cm height could have taken an average thousand years to be covered and sealed!), it is impossible to determine the duration or the contemporaneity of the elements of some heaps of structures as, for example, that of Fig. 6. Density of structures at Pedra Furada is measured as total surface/time and changes along time, not only for obvious taphonomic causes (the younger the layer the richest the content of preserved structures), but also for (unknown) cultural and ecological reasons. In the PF phase, all over the second half of upper Pleistocene, density is higher in the PF2 layer, and not at the beginning (PF1) nor at the Pleistocene-Holocene transition (PF3), when the

P

Pedra Furada, Archaeology of, Fig. 6 *Left*: hearth N 30, boarded by sandstone fragments and quartz cobbles, Trench 6; note the fine gravelly matrix of the sediment. *Top right*: position of structures in Trench 6, phase PF 2, between 25 and 33 ky BP. Hearth N 30 in *red*. *Bottom right*: vertical situation along the 1 m band. (Modified from Parenti 2001)

site seems almost abandoned or very rarely frequented (cumulative distribution of PF phase in Fig. 2: 7). The same is true for Holocene layers (*Serra Talhada* and *Agreste* phases), when the shelter, undoubtedly, had a more permanent and, maybe, ritual function in the context of a dense settlement system of the whole *Nordeste:* in the lower Holocene (*Serra Talhada*), density is higher than in middle Holocene (*Agreste*) when a critical decrease both in demographic and cultural terms seems to have affected the whole central Brazil, as already pointed out by Araujo et al. (2005).

Stone tools at Pedra Furada in Pleistocenic layers are the core of contention. After having been identified as such on the basis of a detailed study of natural forces acting on the talus cobbles from waterfalls, 595 stone artifacts from quartz and quartzite cobbles and pebbles have been described in *Pedra Furada* phase, subdivided as follows: 196 in PF1, 273 in PF2 and 126 in PF3. Among them, some are undoubtedly trimmed with unifacial or bifacial technique (Figs. 4, 7 and 8), but many others – possibly geofacts – exibit at least clear relevant macrowears (Parenti 2001: Plates 74, 75, 92, 93, 97).

Quartzitic cobbles have been flaked, mainly in order to obtain expedient cutting edges or cores, but intensity of raw material exploitation changes throughout both the *Pedra Furada*, *Serra Talhada* and *Agreste* phases, as shown by the ratio of the number of flake scars >10 mm to weight (kg), which is as follows: PF1: 7.5; PF2: 6; PF3: 5.8; ST1: 10; ST2: 15: AG: 8. These data point to a lesser exploitation of local low material in both of the last layers of each phase: PF3 and AG. The ratio of bifacial to unifacial core tools obtained from local raw material decreased constantly from Pleistocene to Holocene (Table 1), with a slight increase in the ST2 layer, when the shelter probably gained its maximum population density.

In spite of the ambiguous nature of some naturally trimmed (but probably used) flakes or fragments, the only retained by some hasty critics, many artifacts from Pleistocenic layers show clear evidence of technically coherent trimming sequences, such as the examples exposed in Figs. 7 and 8. Many others are exposed in detail in Parenti (2001, plates 53-55, 57, 60, 62, 65, 67, 71, 73, 81, 83, 87). For the whole *Pedra Furada* phase, from a strictly typological point of view – perhaps scarcely useful in the case of informal tools – the toolkit is composed by choppers and chopping-tools, cores, simple scrapers and trimmed flakes, with some notched pieces and denticulates.

After a chronostratigraphic or archaeological gap between 14.3 and 10.4 uncal. ky BP in the first half of Holocene (i.e., Paleoindian and Archaic period in cursory subdivision of Brazilian prehistory), the groups of *Serra Talhada* and *Agreste* phases, although maintaining the exploitation of local cobbles for the obtention of cores

Pedra Furada, Archaeology of, Fig. 7 PF1 multi-purpose artifact, 18,467: unifacially trimmed quartzite pebble, with flaking sequence: (*1*) two parallel flake-scars A and B; (*2*) longitudinal splitting C, because of its use as hammer; (*3*) centripetal flake-scars *D* and retouch macrowears on distal cutting edge *E*. (Modified from Parenti 2001)

and heavy-duty tools, shifted to a more complex lithic technology, integrating different raw materials with more intense core reduction sequences; this led to a true *débitage*, especially on exogenous brown chert, for the obtention of a typical unifacial toolkit: scrapers, *limaces*, and end-scrapers, some of which have been thermally treated (Parenti 2001, Pl. 100). The persistence of a cruder tool manufacture with local raw material has been often observed in brazilian prehistory until very recent times, and is documented also in the nearby shelter of Sitio do Meio (Parenti et al. in print).

Some 950 red and white figures are painted on Pedra Furada sandstone wall, apparently spatially uncorrelated with the archaeological features below. In other sites of the area, figures of the same "style" or "tradition" have been dated, for the most, at the first half of Holocene, a very rich period for central and Northeastern Brazil from a

Pedra Furada, Archaeology of, Fig. 8 *Top*: PF2, 16,998: unifacially trimmed quartzite pebble, probably a core. Average flaking angle of 70°; cortical portion preserved in the middle; the flaking sequence has been established on the basis of the disposition both of flake-scars and visible *lancettes* inside them; bottom: two PF2 cores; both have been obtained by the same trimming sequence. 4430–1: orthogonal core on quartz cobble. 15,891: orthogonal core obtained on quartzite cobble; lower view: double, synchronous, split fracture, due to percussion. (Modified from Parenti 2001)

demographic and cultural point of view, just before the so called "archaic gap" of Brazilian prehistory (Araujo et al. 2005).

Organic remains have been recovered only in Holocenic deposits, because of the acidic (Ph4) siliceous sediment. In *Agreste* e *Serra Talhada* phases, scanty bone fragments of medium to small extant *taxa* are documented, but a rich coprolite assemblage (both animal and human) has been recovered, providing precious insights about lower Holocenic vegetation, archaeobotanic practices (Chaves and Renault-Miskowsky 1996; Chaves 2000) and palaeoparasitology (Araujo et al. 2008). This last, particularly, has (indirectly) proved the existence of at least two maritime migration waves to Americas in the early lower Holocene, because Helminths eggs recovered in human coprolites from ST2 layer cannot have been survive in cold Beringian climate (Montenegro et al. 2006). Charcoal remains from fireplaces, or purported natural fires or both, have been entirely collected from top to bottom of *Pedra Furada* layers and their anthracological study (under the responsibility of Rita Scheel, *Museu Nacional*, Rio de Janeiro) will provide one of the most long lasting palaeobotanical sequences in the Neotropic.

In the context of Brazilian archaeology, Pedra Furada evidence has been received with skepticism by many scholars, for pure academic reasons, but also because the majority of them lack familiarity with the Northeastern landscape and geoarchaeology. In any case, between the end of excavations (1988) and the final report (2001), Pedra Furada gained useful complementary information from some other important sites in the region, especially from close limestone caves and fossil-bearing deposits, such as Toca da Barra do Antonião, Serrote do Artur, Serrote do Sansão, Garrincho (Guérin and Faure 2008). In this last site, some 20 km SW from Pedra Furada, human fossilized remains (one parietal fragment, one lower incisive and a fragment of jawbone with an upper molar) were recovered below a calcitic duricrust dated at 10,020 ± 290 uncal. Years BP (GIF 9335), along with a rich Pleistocene megafauna directly dated at 12,170 ± 40 uncal. Years BP (BETA 136204) (Guidon et al. 2000). They pertain to *Homo sapiens*, but their "archaic"–quite robust traits – according to the authors, point to a local development of prior populations derived from the ancestral stock that firstly peopled the region.

International Perspectives

Today (2012), the whole issue of the Pleistocene peopling of the America is quite "frozen" in mainstream literature, and this is not, in my opinion, an unfavorable situation for the progress of a "normal" science in Kuhn's terminology. In South America and Brazil, particularly, prehistoric research with a more prominent palaeoenvironmental and geoarchaeological tone is finally on the way, which is of crucial relevance because of the overabundant attention paid to more visible phenomena (such as rock art or formal lithic typology) in the past decades. Peda Furada has been of great importance for the debate of the antiquity and modalities of peopling of South America, and still holds consistent potential as a reference site for eastern Brazilian lowlands. With its continuous paleobotanic and well dated record, the shelter can fill the geographic gap in paleoclimatic sequence of tropical South America, between the better studied areas of the Amazon basin and Southern Brazil. From a strictly anthropic point of view, Pedra Furada – besides being a reference at regional scale – can be integrated in a true global debate about (dis)continuity and gaps in the archaeological record of many area of the world, such as South Africa, central Asia, northern Europe and many others.

Future Directions

Pedra Furada has not yet definitely and fully been accepted in archaeological literature, and it will probably remain in this limbo situation until the discovery of robust and dated palaeoanthropological evidence in the region. Nevertheless, it is worth noting that the site has produced some true testable hypotheses about palaeoenvironments and regional settlement systems, as follows: (1) a clear cultural discontinuity between upper Pleistocene and lower Holocene, as suggested by lithic traditions; (2) the existence of a humid phase between 10 and 9 uncal. Ky BP, as suggested by gravel lens of unit 3 (Fig. 3) and by the erosion and falling rock at nearby shelters of Perna, Sitio do Meio and Antoniao; (3) weak interaction between man and megafauna, the former being in no way responsible for the (mostly Holocenic) disappearance of the latter; (4) Pleistocenic groups had, on the whole, a weak territoriality, probably correlated with the very low demographic density, indicated by the scanty site occupation in this period, the absence of an intra-site web system, and the weak transport

of lithic products outside the shelter; (5) the (rare) Pleistocene sites of the region could have a lesser proportion of core-tools, because these latter are overabundant at Pedra Furada, given the proximity of *cuesta* cliff; (6) the absence of chert and calcedony in the PF phase is due to its non visibility for pedogenetic reasons or for cultural causes (see point 4) or both; (7) the bimodal distribution of structure dimension in Pleistocene layers is due to functional reasons: the smaller could have been combustion structures, while the larger probably served as contention, space arrangement or pavement structures; (8) at the very beginning of Holocene a true regional integrated system is in place, in which some sites have specialized functions as quarry or ritual place; (9) in lower Holocene, local quartzite has been heath-treated for the making of some formal tools; and (10) rock art of *Nordeste* tradition (lower Holocene) is not specially bound to a specific site function.

New research based on the relevant Pedra Furada archaeological sequence will be useful and fully acknowledged only if it is truly interrelated with palaeoenvironmental studies in a continental perspective.

Peiligang: Agriculture and Domestication

Li Liu
Department of East Asian Languages and Cultures, Stanford University, Stanford, CA, USA

Basic Site Overview

Peiligang (2 ha) is an early Neolithic site, located near the Peiligang village in Xinzheng county, Henan Province. It was first discovered in the 1960s, and subsequently excavated in four seasons during the 1970s. Its cultural deposits measured 1–2 m in depth, and within the excavated area of 2,615 m^2, archaeologists found 22 ash pits, one kiln, and 114 burials. The site dates to c. 6200–5600 BCE (Kaifeng 1978; Institute of Archaeology 1984, 2010: 126–141).

After these excavations, more sites sharing similar material assemblages with Peiligang were discovered in central Henan, and collectively named the Peiligang culture. To date more than 100 Peiligang culture sites have been identified, distributed over a large area of the middle Yellow River valley, including mainly the Huanghuai Plain in central Henan and the Yiluo basin in western Henan.

Peiligang sites can be classified into two types in terms of their environmental settings: those on the alluvial plains and those on hilly areas. Sites of the former type (lowland) tend to be larger in size, with thicker deposits and more elaborate material assemblages, such as Jiahu (5 ha) in Wuyang county and Tanghu (30 ha) in Xinzhengcounty. On the other hand, sites of the latter type (upland) appear to be smaller in size, with thinner deposits,

Peiligang: Agriculture and Domestication, Fig. 1 Peiligang culture pottery. (After Institute of Archaeology 2010: Fig. 3–10)

less variety among artifacts, and pottery vessels of simpler form, made more crudely. These contrasting traits may reflect different subsistence-residential strategies and various levels of social complexity. The sites on alluvial plains may have had higher levels of sedentism and more complex social organization, while some of those in hilly areas are likely to have been seasonal camp sites or small villages (Liu and Chen 2012: 141–150).

Peiligang culture sites are further divided into two regional variants based on their geographical distribution and material remains; these are the

Peiligang: Agriculture and Domestication, Fig. 2 Peiligang culture stone tools. (After Institute of Archaeology 2010: Fig. 3–11)

Peiligang type in the north and the Jiahu type in the south. Some 40 radiocarbon dates from ten sites show that most Peiligang sites date to c. 6200–5500 BCE, although the earliest phase at the Jiahu site dates to as early as 7000 BCE (Institute of Archaeology 2010: 126–141).

Pottery of the Peiligang culture is characterized by various functional types, distinguishable as cooking, serving, and storage vessels, many of which are customarily referred to as tripods, due to their three-legged design (Fig. 1). Lithic implements include both chipped and ground tools, and the latter are morphologically classified to axes, adzes, chisels, spades, sickles, and knives. Microliths have also been found. Grinding stones made of sandstone, including slabs and elongate handstones, have often been uncovered from burials (Fig. 2).

Most dwellings were small semi-subterraneous houses, normally less than 10 m^2 in size. They were round, oval, square, or irregular in shape. Deceased were often buried in cemeteries, separated from residential areas. Tombs were rectangular shafts with single interment, but some secondary burials with multiple interments have also been found. A majority of tombs was associated with grave goods, including pottery vessels and stone tools, which seem utilitarian in nature. The quantities of grave goods vary among tombs, ranging between one and a dozen in most cases. At Jiahu, however, some tombs were furnished with ritual objects, such as bone flutes and turtle shell implements, a phenomenon rarely seen in other sites.

Evidence of Early Agriculture

Several Peiligang culture sites have revealed millet remains (*Setaria italica*), and Jiahu has revealed rice remains (*Oryza* sp.). These are among the earliest domesticated cereals in North China. Floral remains recovered from Peiligang sites, however, are more heavily weighted toward wild plants (e.g., soybean, acorns, walnuts, hazelnuts, jujube, plums, and water caltrops) than toward cultigens (rice and millet) (Table 1). The importance of wild plants in the Peiligang subsistence is supported by functional study of grinding stones, which occupy substantially high proportions of the Peiligang culture toolkits. Starch and usewear analyses of grinding stones from Egou and Shigu indicate that they were used for processing acorns, beans, tubers and millet (Liu et al. 2010).

Dog and pig were domesticated, while a wide range of wild animal species was hunted, such as deer, wild boar, raccoon dog, and rabbit. Fishing was also a part of subsistence economy (Henan 1999).

Peiligang: Agriculture and Domestication, Table 1 Plant remains from major Peiligang culture sites (Liu and Chen 2012)

Site	Cultigen	Wild plants
Jiahu	Rice	Wild rice, acorn (*Quercus* sp.), water caltrop, tubers, lotus root, walnut, wild grape, soybean
Peiligang	Possible foxtail millet	Walnut, Plum, jujube
Shawoli	Possible millet	Walnut, jujube
Egou		Acorn (*Q. acutissima*), walnut, jujube
Shigu		Hazelnut, walnut, jujube, elm fruit
Shuiquan		Acorn (cf. *Q. variabilis*), walnut (*Juglansmandshurica*), jujube (*Zizyphus jujube*)
Tieshenggou		Fruits and nuts
Wuluo Xipo	Foxtail millet	Nuts, foxtail grass, Panic, mannagrass
Fudian	Foxtail millet	

Peiligang culture has long been regarded as having achieved a substantial level of agriculture, but the archaeological record shows that the people actually practiced broad-spectrum subsistence strategies, in which food production was only a minor component of the economic system.

Peking Man

Rhiannon Margaret Agutter
College of Humanities, Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Introduction

Peking Man (*Homo erectus pekinensis*) is an example of *Homo erectus*. The first evidence for Peking Man was discovered in 1921 by Austrian paleontologist Otto Zdansky who found a single hominin molar within a deposit at a quarry near the Chinese town of Zhoukoudian (then Chou K'ou Tien) approximately 30 miles (around 48 km) from Beijing (formerly Peking) (Reader 1988: 94). Further evidence of Peking Man came in 1927 when a third tooth (Zdansky had found another while sorting the excavated material (Reader 1988: 99)) was discovered by Swedish researcher Dr. Birger Böhlin. This tooth was turned over to Canadian anatomist Davidson Black for study (Conroy 1997: 303). Black considered the tooth to belong to a previously unknown species of hominin, the oldest discovered on the Asian mainland, which he named *Sinanthropus pekinensis* (Black 1927). The first Peking Man skull was discovered by Chinese paleontologist, archaeologist, and anthropologist Whenzong Pei on the 2nd of December 1929. This skull revealed that, despite slightly different dentition, Peking Man was not in fact a member of a new genus but rather an example of *Homo erectus* and very similar to Java Man (formerly *Pithecanthropus erectus* now *Homo erectus erectus*) (Reader 1988: 106). By 1937 fourteen skulls, eleven mandibles (lower jaws), and 147 teeth, along with seven femurs (upper leg bones), two humeri (upper arm bones), a possible clavicle (collarbone), and a single carpal (wrist) bone belonging to *Homo erectus pekinensis*, had been discovered at Zhoukoudian (Reader 1988: 107). Excavation was halted by the outbreak of the Second Sino-Japanese War and the subsequent Japanese invasion in 1937; however, the Peking Man fossils remained safely stored in Zhoukoudian at the Cenozoic Research Laboratory until 1941 when, due to growing American-Japanese tensions during World War Two, the bones were packed for shipment to America. Sometime in late 1941 all the Peking Man fossils, except for the few teeth discovered by Zdansky, vanished and have not been seen since (Conroy 1997: 304). A number of drawings, photographs, and a full set of casts did make it to America, however, in the hands of the head of the Cenozoic Research Laboratory, Franz Weidenrich (Reader 1988: 108). Excavation at Zhoukoudian resumed in 1949 and has continued periodically since, uncovering a number of cranial and postcranial bones (Reader 1988: 109). The most recent excavations at Zhoukoudian, beginning in 2009, have revised previous dating of the site and of Peking Man (Shen et al. 2009).

Definition

Peking Man is the common name of a collection of fossilized specimens first discovered in Zhoukoudian, China, in 1921 and known scientifically as *Homo erectus pekinensis* (Reader 1988; Conroy 1997). In the 1970s Peking Man was dated to around 230–500 kyr (1000 years)

based on fission-track dating of Locality 1, layer 10 (the lowest level to contain hominin fossils) and $^{230}Th/^{234}Ur$ (thorium/uranium) dating of layers 1–3. These dates were supported by later electron spin resonance and $^{231}Pa/^{235}Ur$ (protactinium/uranium) and have been generally accepted as correct (Shen et al. 2009: 198). However, more recent work conducted at Zhoukoudian has offered an older date range of around 680–780 kyr based on $^{26}Al/^{10}Be$ (aluminum/beryllium) dating methods (Shen et al. 2009).

Key Issues/Current Debates/Future Directions/Examples

The Use of Fire

A number of thick ash layers have been identified at Zhoukoudian, some being up to 6 m in depth (Conroy 1997: 316), which indicate extended periods of burning. This has commonly led to the conclusion that Peking Man had the ability to create and manage fire even from its earliest occupation and continued this practice for long stretches of time. While Peking Man's use of fire is generally accepted within the scientific community, some have argued against this view. In 1985 Lewis Binford and Chuan Kun Ho argued that while there was certainly evidence of burning at Zhoukoudian, the ash layers were most likely not hearths as they were far too thick and spread out. Instead, Binford and Ho argued that the "ash" layers were probably the result of burning guano deposits (most likely owl droppings) which either spontaneously combusted or were ignited by an outside source (Binford and Ho 1985: 429), as evidenced by the large number of rodent bones and comparative lack of hominin remains associated with the deposit. While this theory has its supporters, many continue to believe in Peking Man's use of fire at Zhoukoudian.

The Use of Stone Tools

Many thousands of individual stone artifacts made of sandstone, flint, and quartz (Conroy 1997: 310) have been discovered at Zhoukoudian, some in direct association with hominin remains, many not (Binford and Ho 1985: 429). Nevertheless, artifacts discovered as deep as layers 8–11 (Locality 1) indicate that Peking Man was utilizing stone tools from as early as 460–420 kyr (Conroy 1997: 313). Tool types discovered at Zhoukoudian include points, burins (chisel-like artifacts), scrapers, and choppers, many of which display evidence of retouching (Conroy 1997: 313) and at least three different techniques (anvil percussion, direct percussion, and bipolar percussion) for making the tools seem to have been employed. Over time Peking Man's toolkit appears to have improved and evolved; tools recovered from the earliest occupation layers are generally larger and are made using all three techniques, while those from higher levels (dated to around 300–230 kyr) are smaller and more refined, and the bipolar percussion method is most common (Wu and Lin 1983). In general the stone artifacts discovered at Zhoukoudian provide greater evidence for evolution adaptation and change in Peking Man over time than the fossilized hominin remains.

Peking Man's Diet

While few of the stone tools found in association with Peking Man could be directly considered as weapons, there is a general assumption that *Homo erectus pekinensis* was both a hunter and a gatherer. Indeed the large amount of faunal remains – including wild pig, mouse, rat, frog, bat, hare, hedgehog, bear, horse, a huge amount of deer, and a number of other animals (Chia 1975: 42) – seem to suggest that some sort of predator was utilizing the caves at Zhoukoudian; whether this predator was human, however, is often debated. A large number of hyena bones have also been found at Zhoukoudian, and the guano deposits indicate that owls also made a home in the caves. Binford and Ho (1985: 425) have suggested that the composition of the faunal remains, including the parts and types of animals heavily represented (most notably the deer), and their location in dark parts of the caves, suggests that their accumulation at Zhoukoudian is more likely due to hyena activity than it is an indication of hominin hunting. However, some burned remains and some hominin modified antlers (Chia 1975: 31) discovered in the deposit do suggest that Peking Man was utilizing the local fauna, though whether this was through hunting or

simply scavenging is unclear. Floral remains at Zhoukoudian are far less common. A number of hackberry seeds have been discovered at the site, but it is hard to determine if they are an indication of Peking Man's diet or if they simply fell, through sinkholes, into the caves.

Cannibalism

There has been some suggestion, since the discovery of Peking Man, that cannibalism may have occurred at Zhoukoudian. This conclusion of cannibalism is based mainly on the longitudinal splitting of a few postcranial bones, the burning of a very small amount of hominin remains, the breakage pattern displayed in the mandibles (lower jaws), the lack of facial regions among the skulls, and some fractures, groves, and abrasions on a number of the skulls (Binford and Ho 1985: 414). While the theory of cannibalism continues in some texts and the popular media, it has generally been discounted among the scientific community as the damage to the bones can be explained by either common taphonomic processes or the actions of other, nonhominin, predators.

Evolution of People in Asia?

From discovery to the present day, a number of the debates regarding Peking Man have linked to the evolution and dispersal of humans throughout the world. While the majority of the international scientific community supports what is popularly known as the "out of Africa" hypothesis – the idea that modern humans (*Homo sapiens*) evolved from a small population in East Africa and only began to move throughout the world within the last 100,000 years, replacing previous populations of *Homo erectus* and other hominin genera as they spread – the official view in China is for a rather different method of human evolution. Chinese scientists generally advance a more "sinocentric" (Sautman 2001: 99) view on evolution, suggesting that the earliest hominids evolved within modern Chinese borders and that modern humans developed independently in Asia several hundred thousand years before they did elsewhere. This belief in multiregional evolution posits that modern humans evolved from various pre-*Homo sapiens* populations around the world (Howells 1983: 298), the Chinese from Peking Man, Australian aboriginals from Java Man, and Europeans from Neanderthals (Sautman 2001: 100) due to unique morphological features which persist throughout certain region's populations. Some Chinese scholars still support the idea posited by Franz Weidenrich in the 1930s that Peking Man was a direct ancestor to modern Chinese people and that *Homo erectus pekinensis* proves that Chinese people have existed since the very earliest stages of humanity (Sautman 2001: 97). At present fossil, genetic and linguistic evidence supports the "out of Africa" hypothesis much more firmly than the "sinocentric" viewpoints (Sautman 2001: 98).

Penin, André

Fabiana Rodrigues Belem
Museum of Archaeology and Ethnology, University of São Paulo, São Paulo, Brazil

Basic Biographical Information

André Penin Santos de Lima (1976–2012) (Figs. 1 and 2) was a Brazilian archaeologist, born in São Paulo in 1976. He graduated from law school at the Pontifical Catholic University of São Paulo in 1998, but it was at the University of São Paulo that he pursued his career in archaeology. He graduated in history (2000) before achieving a Master's degree (2005) and Ph.D. (2010) in archaeology at the Museum of Archaeology and Ethnology.

In 2009 André Penin became a professor of archaeology with the Archaeology Department at the Federal University of Rondônia, near the Brazilian frontier with Bolivia. He was also affiliated as a professor at the State University of Amazonas and a member of the editorial board of the *Veredas Amazônicas* Journal.

Professor Penin's main areas of interest were heritage, archaeology, and cultural resources management. He was an active and engaged member of the forums regarding those subjects, as well as on the national meetings of the archaeological community, where he was always posing questions and presenting works regarding the political background of the Brazilian archaeological scenario. He was engaged in the three domains in which archaeology takes place in Brazil: the academy, cultural resources management and "the other side of the desk" – as he used to say – as he spent time as a technician at the Institute for National Artistic and Historical Heritage (IPHAN), in the states of the São Paulo and Santa Catarina.

André Penin died tragically at the beginning of 2012.

Major Accomplishments

At the beginning of his career as an archaeologist, Penin focused on the lithic industry and shell mounds of the southern and southeastern Brazilian coast. It was these subjects that he pursued his

Penin, André, Fig. 1 André Penin at Santa Catarina, Santa Marta's sambaquis, 2008

Penin, André, Fig. 2 André Penin, in his office at the University of Rondonia, 2009

thesis, titled *Analysis of the Formative Processes of Capelinha Archaeological Site – Setting up a Microregional Context*.

In 2005, André Penin started to work at IPHAN, first at São Paulo and later at Santa Catarina. It was within this scenario that he was able to draw on his background as a lawyer and engage in the politics of Brazilian archaeology. This experience was later translated into his dissertation in 2010, *Academic, Contract and Heritage. Different Views of the Same Discipline: Archaeology* (Penin 2010), in which he analyzed the practical consequences that the law has on archaeological practice in addition to conducting a legal analysis of the legislation concerning archaeology.

In 2009 he finally became a professor fulfilling his desire to teach – an activity that he carried out with the same commitment and engagement that he displayed in the other domains of Brazilian archaeological practice. His early and tragic death greatly affected the archaeological community in Brazil. Though he was young, he left a legacy in terms of his professional conduct and commitment to ethics in Brazilian archaeology and through his passion for teaching and research, which has inspired others to follow in his footsteps.

People as Agents of Environmental Change

John H. Walker
Department of Anthropology, University of Central Florida, Orlando, FL, USA

Introduction

When archaeologists consider people as agents of environmental change, they open a group of related discussions, some of which have been going on as long as archaeology has been recognized as a discipline. These same issues are becoming more important to wider audiences, and archaeologists now have opportunities to contribute to conversations in other disciplines, as well as to decisions made in the public sphere. As archaeologists study relationships between people and the environment in their efforts to study the past, categories such as "nature" and "culture" can be seen as terms used to achieve political and economic goals. Those who have a stake in whether and how people change the environment will always be interested in the answers to these questions.

Historical Background

People value environmental knowledge because they construct their economic lives out of it. Before considering whether people changed the environment, it seems clear that people can change themselves, into a spectacular variety of different ways of interacting with the environment, at every scale. Fishers, farmers, nomads, urbanites, traders, and crafters are a few of the distinctive ways to make a living from the environment. This diversity of human activity is impossible to separate from its corresponding range of relationships that people have with the environment.

Study of the environment in archaeology is integral to the discipline. Archaeology was born in the realization that geological strata were correlated with different categories of artifacts. The three-age classification (Stone, Bronze and Iron Ages) was closely related to the development of stratigraphy as a tool in geology. Archaeologists and paleoecologists used pollen to reconstruct past vegetation, analyzed glaciers to understand the geological past, and then used those reconstructed environments as context for the evidence of prehistoric life. Reconstruction of the environment has always been a part of archaeology. In broad strokes, this historical context is an ecology or an interaction between three distinct kinds of ideas. These three categories make a tidy set, but just as with any classification, the phenomena in question (the practices of different researchers) in fact combine features of all three.

The first is the founding ideas of the biological and historical sciences, dating to the nineteenth century. After Darwin and Wallace put forward the idea of natural selection, nature was thought of as a variable, rather than a constant. Without this insight, archaeology (and coincidentally, anthropology) would not be recognizable. Because people were seen as part of the universe described by natural selection, the question of how human societies came to be was reopened. This question would be answered against the backdrop of environmental processes that had operated throughout the history of the earth, and even the solar system. In this view of environment, and its relationship with humans, the tools of biological science, chemistry, physics, and geology are used to better understand the current environment and its history through the operation of these universal processes. This powerful mode of thought lies behind the development of all the historical sciences, and accounts for much of the relevant research today.

Individuals are hard to distinguish in the archaeological record, and archaeologists interested in environment generally focus on communities or societies. Ideas about the most useful way of thinking about communities of people vary widely. American archaeology (via its disciplinary roots in anthropology) often views groups of people as having culture, a set of ideas that has influences or perhaps determines how they interact with the environment. Archaeology in Europe (and the UK) is perhaps more oriented toward the idea of society; it is less concerned with ideas that people might share, and more with how groups of people are organized and how they function.

The second idea that contributes to archaeological understanding of the environment dates to roughly the middle of the twentieth century, in conjunction with many significant advances in biology, cybernetics, and ecology. Translated into anthropology (or at least American anthropology), this resulted in a surge of interest in cultural evolution, ecology, and human ecology. The environment is conceived as constantly changing, but perhaps predictable as it follows feedback loops to maintain key variables (population, for example) within sustainable bounds. For example, populations of deer and wolves might vary, but because they are mutually dependent, they oscillate around a stable mean value. This idea is perhaps equally influential as the first, and certainly has resulted in useful research on how human communities relate to the environment in complex ways, whether through rituals associated with sweet potato gardening and raising pigs, or relationships between population and resource among nomadic peoples, or intensive farmers. Ecological points of view often emphasize balance between people and the environment, but people often fail to maintain such relationships.

The third type of idea acknowledges that nature is changing, but because of the efforts of field ecologists (Botkin 1990), it seems that self-regulating, equilibrium relationships do not often manifest themselves outside the laboratory. Instead, ecologists and interested social scientists have converged on a combination of ecology with history, often termed historical ecology. Ecological relationships are still central, as the inputs and outputs of any part of a system impact all the other parts, but the historical contingency of these relationships becomes the center of attention (Crumley 1994). In this point of view, nature or environment is seen in intimate connection with people, but large patterns are difficult to discern. The way to build such understandings is taken from history, and archaeologists and biologists alike study the local contexts and interactions between people and the environment to build larger theories.

The interplay between these three categories leads to the examination of issues of agency and scale. The idea of agency raises the question of whether intentionality is important to anthropogenic environmental change. For these purposes, anthropogenic change need not be intentional in order to qualify as environmental change. Agency refers to how humans cause change, whether or not they know what they are doing. For example, examining changes in soils over time through the addition of organic inputs like charcoal, it may not be clear whether the changes were intentional or not. Intentionality can also be difficult to define in the archaeological record, when juxtaposed with the different groups of people that might be associated with aspects of the archaeological record. Archaeologists are often more comfortable with what happened in the past than with what people in the past thought was happening.

The question of scale is crucial to describing change and its significance. Archaeologists are concerned with longer periods of time, so that often a change that takes less than a generation is instantaneous. On the other hand, archaeological evidence can establish the presence and importance of long-term trends, over generations, centuries, and millennia. One key question that runs through the history of archaeology, historical sciences, and history is how different scales relate to one another, especially whether causes can be found more at one scale than at the others.

Key Issues

We can define environment as the geological, climatological, biological setting within which people act. The question could then be whether people are capable of moving the scenery around on the stage on which they find themselves. Making this strong distinction between people and the environment as actors and scenery allows an argument to go forward, but the dichotomy itself is part of the theoretical discussion. Different people think of the relationship between people and the environment in very different ways. Because archaeologists and other scholars are also people, they are trapped within this frame of reference. Anthropologists have described many individuals and groups of people who do not draw the line between people and animals in the same place as many westerners. Case studies of how people have changed the environment have made it clear that the distinction between nature and culture is not easy to maintain. What follows is a set of examples in rough chronological order, from human ancestors to the archaeology of the current global political economy.

People use fire to clear grasslands, cook food, warm houses, and hunt animals. Thought of as a technology, the control of fire changes human ecologies tremendously in and of itself, and also as the prerequisite for other technologies: pottery and metallurgy, for example. Although the earliest use of fire has been a controversial topic, recent research suggests that the use of fire predates the human species, as usually defined. If fire was in use by human ancestors and then humans for one million years or more (or perhaps 40,000 generations), then the environment and human communities have been in complex relationships for long enough time to affect both human and landscape evolution. Acting directly on plants and animals, fire is used to favor savanna and fire-tolerant or dependent plants over other forests, to hunt animals on a larger scale, and to open up new sources

People as Agents of Environmental Change, Fig. 1 Large pre-Columbian raised fields near Santa Ana del Yacuma in the Bolivian Amazon. The differences in color are caused by the effects of burning the savanna. Individual fields average about 20 m by 200 m

of food through cooking (Fig. 1; Pyne 2001). Indirectly, the use of fire for other purposes, from cooking to making pots to keeping warm, results in demands for fuel that have further effects, and create processes that generate their own momentum (Bateson 1972). No other process or tool is easier to use and still produces such a dramatic range of profound changes in the environment.

A broad category of interactions includes those by which humans domesticate plants, animals, and landscapes. Domestication is a process that changes both humans and other species biologically, geographically, socially, and culturally. Over the course of several thousand years, corn (*Zea mays*) went from an unassuming tropical grass to a hybridized monster that cannot survive outside a complex, industrialized agriculture integrating genetic engineering, chemical fertilizers, herbicides, world markets, and land-grant universities (Piperno and Pearsall 1998). The changes in the human consumers of corn are equally startling. Among animals, the changes in domesticated animals can be seen through faunal analysis, as these species are also integrated into specialized ecologies. But even among animals that are not changed genetically by farmers, the movements and migrations of species that are hunted by humans, used as pets, or who follow human settlement have tremendous effects around the world. This effect is particularly visible on islands, but was by no means limited to them (Kirch and Hunt 1997). Humans also move earth and manipulate fire and water to favor some ecological communities over others. Realizing that fish are trapped in an oxbow lake, or that animals are limited to high ground during a flood season, allows people to predict and take advantage of regularities in the environment, without expending the effort to domesticate plants and animals at the genetic level.

In many cases, these manipulations of the environment, at many different levels, led groups of people to create and maintain ecologies that are usefully thought of as common pool resources (Ostrom 1990). Forests, often greatly modified and managed by people, are the result of practices like pollarding, coppicing, selecting for particular trees, harvesting firewood, fruits, and managing populations of animals. Some landscapes have documented histories of hundreds or even thousands of years (Rackham 1989). The scale of this management, especially in the tropics, is potentially very large (Balée 1998). Another group of managed resources are fisheries, both fresh and salt water. One of the first topics of research for the anthropologists, historians, and social scientists who study the management of common pool resources: Fisheries are amenable to archaeological research through the analysis of paleodiet

combined with settlement archaeology to study changes in population over time.

The often-arid landscapes of the Near East have been the stage for human history for many tens of thousands, and perhaps hundreds of thousands of years (Wilkinson 2003). The Near East is a palimpsest of landscape features that were built and used over thousands of years. Irrigation channels, threshing floors, roads, caves, tells, trails, and paths, all "written" on top of each other and then rewritten. Many of these landscape features also contain historical and cultural significance for their creators and descendants. These links and these relationships are very important today, and presumably also in the past. If a group of people can change the landscape by piling rocks into a monument, that act can have consequences over the long term that are belied by the simplicity of its immediate consequences. Again, the link between what people think about the environment, and how they relate to one another within the environment, is of first importance. Historical examples like irrigation systems in eastern Spain provide evidence about how human institutions and landscapes are related, over many generations. Archaeologists have uncovered widespread evidence of how pre-Columbian peoples built terraces, raised fields or chinampas, causeways, canals, geoglyphs, zoomorphic figures, mounds, paths, roads, dams, artificial channels, a huge range of direct modifications of the landscape that in turn shape the flows of fire, water, plants and animals, and permanently change the geography of the places where people live (Doolittle 2000; Lentz 2000; Denevan 2001; Whitmore and Turner 2001; Balée and Erickson 2006). The terraced landscapes of Southeast Asia and South America demonstrate how people invested their labor over centuries to make the landscape more productive, and increase the return on their time. Archaeologists have the resources and expertise to determine, not if a resource or a way of life is sustainable, but whether it was in fact sustained.

Many archaeologists have studied the interactions between people and the environment, not as examples of how people have built complex landscapes, or domesticated huge catalogs of plants and animals, but as explanations for drastic changes that are seen in the archaeological record (Redman 1999). The decisions that humans made about the environment, whether the consequences were foreseen or not, have been used to explain changes, usually in complex societies or "civilizations" around the earth. The collapse of the Maya, or the Tiwanaku, or Indus Valley civilization, to take three examples, is taken to be the result of overpopulation, overexploitation of resources, or of limited flexibility in the face of environmental changes such as drought. Many technological processes require large inputs of resources. Using wood and charcoal for fuel may have led to the local extinction of algarrobo trees on the Peruvian coast. Using wood or charcoal to fire adobe into bricks may have been an important limitation on the construction of Harappan cities in the Indus Valley. And the use of resources on Easter Island is an important issue in debates between Diamond and his critics regarding the fate of the people who lived there before the arrival of Europeans. Examining these ideas brings together natural and social scientists in productive ways, because although geologists or climate scientists might have insight into long-term changes in precipitation, archaeologists or historians might have insight into how societies interact with seasonal and long-term changes.

Are the fates of human societies governed by unchangeable environmental (geographic, biological, climatological) parameters, or is it possible for humans to change the environment, or change the rules? It is possible for humans to farm even on another planet, if they invested enough resources in the effort. Likewise, a swampy environment could be unlivable to one group of people, while at the same time being an ideal place for another group. Such differences might be in part preferences, as when someone would rather have warm weather year-round than cope with ice and snow, but such choices are also always interwoven with economic and political choices. James Scott argues that some societies "took to the hills" and moved to remote mountain environments to avoid the predation of lowland kingdoms (Scott 2011). These cultural ideas are as important as environmental limitations.

A very powerful way of thinking about the creation of systems within groups of people that

relate to the environment is the idea of "second nature" (Cronon 1991). When ideas about nature acquire importance and value separate from the aspects of the nonhuman world, they purport to describe or organize, a second nature is established. When corn, timber, or cotton becomes a commodity instead of a crop, the difference between the plants grown by two different farmers in two different places is flattened out. Trade and interaction between people over grain futures becomes more important than interaction between people over grain, or even between people and plants themselves. Farmers make decisions not based on any local factors that concern plants, animals, labor, or inputs, but based on a market in corn futures that they might never see, but whose effects they feel through subsidies or fluctuating prices. Cronon's insight raises the question of whether there might be other kinds of "second nature" that are not tied to the historical and geographic context of nineteenth century Chicago. Such disconnections between decision makers and the environment certainly occurred elsewhere. In addition to looking for the evidence of environmental change in lake cores or glacier cores, archaeologists might also look ideas about how "natural" things are brought into more and more abstract contexts.

The long-term history of commodities and political economy brings archaeology into contact with history, economics, and sociology, among other fields (Hornborg and Crumley 2007). Historical archaeology, which some have defined as the archaeology of the world through the development of industrial capitalism, has a great deal to offer to the study of environmental change. Industrial processes can be studied using historical documents, but archaeological evidence multiplies the value of historical sources. In the Amazon, for example, a historical archaeology of the many efforts to colonize, develop, and modernize the Amazon would include the story of Jesuit missions, connected to a global effort to establish an explicitly Christian utopia, the story of rubber exploitation, with a network of ports and company establishments, ranging from the empires of rubber barons in Peru and Bolivia, to Fordlandia, the company town established to oversee industrial cultivation of latex, and the construction of the Madeira-Mamoré railroad, intended to circumvent the non-navigable rapids and bring Bolivian rubber to the international market. Archaeology of the past 500 years around the world will be indispensable to understanding how industrialization changed the environment, both in the industrializing core, and the distant peripheries of the world economic system. Finally, the intentionality of pre-Columbian peoples is directly tied to one of many ideas that have been projected from the western imagination onto indigenous peoples. That Native Americans should be Noble Savages, counterexamples to the squalor and desperate violence of the fifteenth and sixteenth centuries in Europe, was perhaps an inevitable story. That the idea of native Americans as counterexample to the environmental destruction of multinational corporations and modern nation states is a new variation on an old idea. This idea allows intentionality to modern people, but denies it to pre-Columbian (and contemporary) indigenous communities. It also can be used against indigenous groups when they fail to live up to an imagined standard of behavior, instead choosing to follow their own self-interest.

International Perspectives

Archaeologists of South America, from around the world, and from South America itself, have a unique take on people and the environment. This stems from the unique relationships that pre-Columbian South Americans had with the environment, and with a recent history of interaction between ideas from different schools of thought from a variety of traditions. South American archaeologists have long been interested in the connections between pre-Columbian people and their shaping of the landscape from the terraces that gave the Andes Mountains their name, to raised fields that seem to correlate with widespread intensive agriculture across the continent, to concepts about nature and the place of people in it, deriving from the increasingly detailed ethnographic literature.

Environment is a habitat where people interact with other nonhuman factors and create a wide spectrum of adaptations to those factors. This is a

line of thinking that is as old as South American archaeology, and the application of a host of new techniques is making it more and more productive. For example, the application of faunal, botanical, and environmental analyses of early sites has shown that before 12,000 years ago, and perhaps much earlier, groups of people in South America were pursuing a wide variety of ways of life. This has upended previous interpretations of the importance of Clovis peoples in the peopling of the New World, not only through the earlier dates, but more importantly through the documentation of ways of life that are manifestly unrelated to Clovis big-game hunters. The refinement of techniques to better recover and analyze faunal and botanical remains has made these developments possible. Advances of equal importance are being made across the continent, showing that the deep histories of the areas outside the focal Andean region are equal partners in any account of continental archaeology.

Many archaeologists are also aware of the debates in cultural anthropology about the relationships between indigenous South Americans (especially Amazonians) and the natural world. Many of these relationships may have parallels in other parts of the world, and they certainly have profound consequences for how archaeologists interpret their evidence to stand for pre-Columbian ways of life. For the Huaorani in eastern Ecuador, trees are at the same time ancestors, links to historical knowledge, and part of the living environment where people spend their lives (Rival 2002). If individual trees, kinds of trees, and groves of trees can all have these meanings for Huaorani, then archaeologists have to consider that botanical remains of trees represent more than resources that people consumed. Cormier shows how people and monkeys are categories that blend together, as women nurse baby monkeys, and monkeys are accorded many of the statuses of humans (Cormier 2003). This is a pattern of interaction with animals that holds for many other species, although the social relationships differ. A strong thread in Amazonian cultural anthropology leads through the ideas that relationships between humans and the nonhuman world are social relations, rather than inert instrumental relations. In short, indigenous South Americans draw the line between humans and nonhumans in a different place, if indeed they draw that line at all.

And finally, archaeologists are reckoning with the understanding that the earth itself is a living thing. This is true at the level of soil science, where recent studies have focused on the question of how Amazonians manipulated soil properties to create new kinds of soil that have long-lasting properties, thereby changing the plant and animal communities based on those soils (Glaser and Woods 2004). These studies go to the heart of the question of agency – whether pre-Columbian communities created ADE soils intentionally or as the by-product of occupation. Such soils, known since the nineteenth century, are now being studied as a possible development alternative, and as a key to the puzzle of pre-Columbian economies, both along the main rivers, and in areas far removed from them. The agency attributed to South American mountains and constructed mounds is a remarkable example of complex relations between humans and the environment (Dillehay 2007). Social relationships between people and mountains, or between people and constructed monuments (which are also archaeological sites), are key to living in the right way.

South American archaeologists and anthropologist come to the idea of people as agents of environmental change by choice, but also by necessity. From what we now know of the long-term history of people on the South American continent, it would be difficult to understand from any one theoretical perspective, much less one which does not account for the social relationships between people and trees, animals, and the earth. There is little agreement on a larger framework for fitting these ideas of the environment into a larger story about the South American past, but the analysis of people as agents of environmental change is now well established in the field.

Future Directions

Changes in the technology of archaeological research are a trend that will influence future

studies. Archaeologists work hard for their data in the field, and while this will always be true, new techniques in remote sensing, recovery techniques, and management of data will plunge archaeologists into increasingly deep seas of data. Although shovels remain the same, archaeologists in 2012 derive chronological information from a wide range of recovered materials: scrape botanical information from artifact surfaces, and model hydrological or ecological processes in great detail over very large areas.

At the same time, the integration of local stakeholders in archaeological decision making will certainly have an equal impact. For many, the distinction between archaeology and ecology might not be all that important, as long as they bring in tourists or scientific and development grants. For others, archaeology has the potential to focus international attention (and funding) on issues of cultural identity that have always been important, but now are positioned to gain influence.

Finally, the environmental change that is underway in the twenty-first century will certainly influence the practice and interpretation of research. For example, some cultural resources will be destroyed by sea levels, but perhaps others will become available as different parts of the globe become more accessible. Some assumptions about the inevitable course of environmental change (such as deforestation) require greater scrutiny (Fairhead and Leach 1996). More significantly, the course of environmental change in the twenty-first century will likely influence strongly the goals and prejudices of archaeologists and stakeholders. Research may come to focus on case studies of environmental disaster in the past, and on examples of sustained societies as well. Although this trajectory cannot be separated from the arena of conflicting ideas in the present, the study of changing societies and environments in deep history is a question that combines archaeology, ecology, environmental reconstruction, history, geology, botany, geography, and other fields to inform decision makers at all scales, from descendant communities to state bureaucracies, to multinational companies.

Today, many are convinced that people change the environment, from a local to a global scale. However, environmental change in the twenty-first century is a divisive political and economic issue. Establishing connections between how people relate to the environment today, and how they did so in the past, can be a powerful rhetorical strategy. To see societies in the past as examples of sustainable ways of life, or as cautionary tales of mismanagement and ignorance, is a powerful argument when buttressed by archaeological data. Likewise the past 100 years have been described as "Something new under the sun," another strong position in current debates over environmental issues (McNeill 2001). Archaeology is more than political rhetoric, however, and research and analysis suggest that in fact, people have been agents of environmental change for many millennia, over most of the surface of the earth, and into oceans, rivers, and the atmosphere.

If people were agents of environmental change for centuries or millennia, this adds a crucial dimension to our understanding of societies in the past. Arguments over how and why civilizations "rose" and "fell" are often made using reconstructions of past environments, and the further study of these relationships is critical. But it also puts today's debates about environment and society into an important perspective. The world today, whether thought of as social, natural, or something else, is affected by processes that have operated for many generations. The accumulated changes of generations of artificial selection have changed corn from a tropical grass to a commodity. In a similar way, the accumulated labor of generations of farmers has produced irrigation ditches, terraces, raised fields, and other agricultural infrastructure, which is crucial to modern agricultural successes. The study of people as agents of environmental change must change several fields, by demonstrating that ancient environments, ancient societies, and the relationship between society and the environment today are all conditioned by these important historical contexts, whether or not the analysis of these case studies yields any kind of universal history or model.

Introduction

The antiquity of humankind in the Americas has been a recurring theme in popular and scholarly thought since the spurious discovery of the hemisphere by southern Europeans. Virtually as soon as Cristoforo Columbo set foot on San Salvador (or Samana Cay) to encounter its native people and future victims, a lengthening chain of questions about the indigenes were posed by the explorers themselves, civil and religious bureaucrats, military men, mercantilists, and the inevitable crass opportunists. Who might these people be? From whence did they come? How did they get here? How long have they been here? Scholars, following the very early lead of Spanish Jesuit missionary and naturalist José de Acosta, eventually came to inquire into the everyday lives of the New World's peoples and how they might have lived. The answers to some of these questions have proven to be resolutely intractable or highly problematic as of this writing, despite a number of significant field and laboratory discoveries.

Historical Background

Examination of the timing, methods of movement, routes, and geographic and genetic origins of human migration into the hitherto unpopulated Western Hemisphere has engaged archaeological inquiry for over 150 years. The last of the Pleistocene migrations by fully modern humans, and arguably the last of the great earthbound human migrations, this journey covered thousands of kilometers over the course of several 1000 years, well after the movement of anatomically modern *Homo sapiens sapiens* out of Africa (ca. 100,000 BP) and central and eastern Asia (ca. 45,000–40,000 BP). Upon their arrival, these first migrants then appear to have quickly spread throughout the entire (and then completely unknown) hemisphere relatively quickly, adapting to a complex and variable array of local climates, landscapes, and biota while also exhibiting concomitantly diverse technologies and lifeways on the landscape in very widely distributed locations.

Scholarly answers to the questions surrounding this migration have achieved varying levels of resolution and consensus, but some aspects – most notably, the physical homeland(s) and specific genetic forbears as well as the timing of the event(s) – have, as noted above, remained intractable and unresolved. It is generally agreed, for example, that the earliest inhabitants of the Americas were at first northeastern Asians. Resolution and consensus begin to break down, however, once one starts specifying precisely where in northeast Asia, as well as the timing (pre- versus post-Last Glacial Maximum [LGM]) and routes of the migration (coastal vs. interior, or both?). Considerable lacunae continue to exist in our understanding of late Pleistocene lifeways in the Americas, moreover, hinging as it does on quite variable data from far-flung sites that are often relatively small, poorly preserved, and ephemeral compared to later (and sometimes overlapping) cultural manifestations.

The confirmation of a deep human antiquity in Europe by a delegation of British geologists and antiquarians visiting the excavations of Jacques Boucher de Crèvecœur de Perthes in the Somme valley of northern France in 1859 soon filtered across the Atlantic. This, in turn, stimulated American academicians to naively seek phenomena of comparable antiquity in the Americas. The ensuing "American Paleolithic" debate would foreshadow later, persistent disputes about the timing of the arrival of the hemisphere's first colonists. The question of an American Paleolithic would temporarily be resolved by the turn of the twentieth century, when – thanks largely to the insistence on rigorous standards of evidence

by Aleš Hrdlička, William Henry Holmes, and others – all claims for an Ice Age human presence in the Americas had been dashed (Meltzer 2015). Prior to the 1920s, the received wisdom was that no humans had entered the hemisphere before the final retreat of the glacial ice and the subsequent inundation of Beringia.

This almost universally accepted position would ultimately be dismantled by another delegation of experts which, in 1927, confirmed Jesse Dade Figgins' claimed association of an extinct species of bison (*Bison antiquus*) with artifacts of indisputable human manufacture in an unambiguous stratified context. The artifact suite notably included delicately made projectile points with bilateral channel flakes or flutes, which were named Folsom after the locus of the discovery. This seminal research not only established that humans were in the Americas sometime before the end of the last Ice Age, but also that they were living among and preying upon extinct Pleistocene fauna.

Four years later, two other discoveries, one near Dent, Colorado, and the other at Blackwater Draw, south of Clovis, New Mexico, revealed more evidence of the apparent hunting of extinct Pleistocene megafauna, in these cases, mammoth (*Mammuthus columbi* or *Mammuthus primigenius*). Associated with these remains was a robust form of bi-channel flaked point which subsequent excavations demonstrated was stratigraphically deeper and thus older than the bison-associated Folsom point. Named Clovis after the nearby community, these points were subsequently reported from much of unglaciated North America as well as portions of Central and South America. Within a few decades, these forms and a suite of loosely associated artifacts came to be regarded as the material culture signature of the hemisphere's initial colonists and were considered to be emblematic of a highly specialized, big-game focused lifeway pursued by rapidly moving spear-wielding hunters.

With the advent of radiocarbon dating in the late 1940s and early 1950s, the Clovis "horizon" was initially fixed at ca. 13,500–13,000 calibrated radiocarbon years before present (cal BP). By the late 1960s, a peopling scenario that held Clovis as the hemisphere's initial colonizing pulse was widely accepted by a great majority of North American scholars and the lay public. Called "Clovis First" in more recent times, its proponents concluded that sometime shortly before 13,500 cal BP, a small group of Paleoindians crossed the Bering Platform dry-shod (as postulated by d'Acosta in 1590), passed through unglaciated Beringia, and then rapidly moved south through the narrow corridor between the waxing and waning Cordilleran and Laurentide ice sheets. Following their transit through the ice-free corridor, these putative first inhabitants of the Americas were then presumed to have spread throughout the entire hemisphere in the span of only about 500 radiocarbon years. Either shortly before, or perhaps during this dispersal, they were also presumed to have invented the fluting of projectile points and used these allegedly lethal weapons to more or less synchronously dispatch some 35 genera of late Pleistocene fauna. This "blitzkrieg" dispersal, as it came to be known, was championed by the late Paul Martin (1967). A crucial corollary to this scenario was the contention that Clovis technology was ancestral to all other lithic tool kits in the entire hemisphere. Although not without its critics, especially in Europe and South America, the Clovis First model became further entrenched by the repeated failure to identify bona fide sites predating Clovis and the apparent support provided by the limited physical anthropological and linguistic data available at that time.

Despite its inherent weaknesses, especially the existence of roughly contemporaneous lithic industries that are clearly technologically distinct from Clovis, the Clovis First paradigm did not begin to unravel until the early 1970s with the discovery of several sites that seriously challenged the Clovis First model. The most frequently cited localities that have precipitated a general acceptance of the existence of pre-Clovis populations in the Americas are Monte Verde in Chile (Dillehay 1989, 1997) and Meadowcroft Rockshelter in southwestern Pennsylvania (Adovasio et al. 1984, 1985, 1990; Carlisle and Adovasio 1982). These two localities yielded durable and perishable artifacts of indisputable

anthropogenic origin in well-defined stratigraphic contexts that were tightly bracketed by multiple internally consistent radiocarbon determinations. Despite continued criticism from some scholars, these two sites nonetheless definitively established a human presence in the Americas at least 1,000–2,500 radiocarbon years before the Clovis First model's presumed crossing of the Bering Strait.

Although Meadowcroft was discovered and documented first, Monte Verde is widely considered to be the first site to have decisively broken the Clovis First peopling scenarios. Located on a small tributary stream, Chinchihuapi Creek, about 20 km northeast of the Gulf of Ancud on the west coast of Chile, Monte Verde is currently the southernmost pre-Clovis site in the hemisphere. Several cultural components have been identified at Monte Verde. The oldest of these components, MV-I, was until recently only known from a very circumscribed deep excavation. As originally defined (Dillehay 1997), the MV-I component consisted of three possible anthropogenic features, eight "scatters" of charcoal, and a suite of some 26 lithic artifacts. Originally thought to date to as early as 38,800–36,620 cal BP, recent re-excavations conducted in 2013 suggest that the age of this occupation, or series of occupations, is probably ca. 18,500–15,000 cal BP in age (Dillehay et al. 2015).

The 2013 excavations yielded additional charcoal, thermally altered bone fragments, and lithic artifacts, with some of the latter sourced to distant quarries. Despite the potentially profound implications of the earlier posited date range for MV-I, which would make this site penecontemporaneous with the earliest generally accepted penetration of modern humans into Siberia, the excavators continue to be very cautious about the age of the first visitation/utilization of the Monte Verde locality (Dillehay et al. 2015). As a result, far more attention has focused on the much more extensively and intensively investigated MV-II component, which is securely dated by well over a dozen conventional and AMS assays on various substrates to ca. 14,800–13,800 cal BP.

Significantly, Monte Verde's MV-II component appears to reflect a semi-sedentary, broad-spectrum adaptation that is fundamentally different in all respects from that modeled for later Clovis populations. As a stream-side residential site that is sealed beneath a postoccupational peat mantle, the component's principal habitation area lies north of the stream and is composed of the structural remains of 12 rectangular, hut-like dwellings made of wood elements and covered with plant material and/or the skins or hides of animals like paleo-llama (*Llama glama glama*). Associated with these structures were four workshop areas, a midden concentration, and a variety of hearths and pits. Excavations in the residential area yielded lithic, bone, wood, and fiber artifacts as well as the remains of more than 70 taxa of plants, including local as well as exotic edible and medicinal varieties. Remarkably, actual specimens of animal tissue and hide were recovered in addition to abundant faunal remains, notably including fragmented, burned, and unburned bones and ivory of a mastodon cousin, the gomphothere (*Cuvieronius* sp.). Directly to the west of the hut complex was another structure with a wishbone-shaped foundation and extensive associated refuse (Dillehay 1997:49).

Collectively, the material inventory from Monte Verde indicates a semi-sedentary subsistence regime that included the exploitation of small game, paleo-llama, and, potentially, larger animals like gomphothere as well as a wide diversity of local and nonlocal plant foodstuffs. The toolkit is dominated by perishable artifacts with a lithic industry that is remarkable only for its expedient character and general lack of temporal diagnostics. Indeed, with the exception of three projectile point fragments with apparent affinities to the Paleoindian El Jobo type, the majority of the durable tool kit can only be called depauperate, with few curated tools and a virtual absence of formalization. Most of the igneous raw materials employed in the production of the MV-II stone toolkit derive from locally abundant glacio-fluvial gravels with fewer than 15% coming from nonlocal sources. In sum, the evidence from Monte Verde indicates an adaptation completely inconsistent with the Clovis First paradigm in chronological, technological, and behavioral terms. The majority of the North American scholarly

community accepts the antiquity of the MV-II occupation at Monte Verde.

More than 10,000 km north of Monte Verde is Meadowcroft Rockshelter, a deeply stratified south-facing rockshelter located on a minor tributary of the Ohio River in southwestern Pennsylvania (see Meadowcroft Rockshelter, this volume). The 11 strata at this site have yielded the longest occupational sequence from eastern North America and one of the longest in the Americas. The site's upper strata (Upper IIa–XI), whose temporal provenance has never been seriously disputed, span the entire Holocene with a terminus ad quem dating to just before the American Revolutionary War (AD 1775–1783). The lower culture bearing strata (Middle and Lower IIa) and their attendant radiocarbon dates, however, have been the subject of four decades of vigorous debate and controversy. Continued criticism has pivoted around alleged contamination of only the 11 oldest radiometric determinations from the site, along with the absence of a final report.

No evidence of any form of contamination has ever been demonstrated despite extensive publication on stratigraphy and the dating issue. As recently noted by Adovasio and Pedler (2013:514), applying the most conservative interpretation of the available chronometric data, the latest or most recent age for the presence of human populations in this portion of the Ohio River basin is in the range of 13,870–12,660 cal BP. Radiometric dates on charcoal from a series of firepits identified in lower Stratum IIa range from 20,476–18,110 cal BP to 16,565–14,085 cal BP. If the six deepest dates at Meadowcroft Rockshelter which are unequivocally associated with cultural material are averaged, then humans were definitely present at Meadowcroft between 17,500 and 16,750 cal BP. The oldest date from lower Stratum IIa that was run on a carbonized bilaterally cut fragment bark-like material is 26,212 cal BP. The configuration of the dated specimen is fully consistent with plaiting strips employed in later Meadowcroft basketry and *may* be a fragment of a basket wall. In any case, it is anthropogenically altered and suggests that the earliest Meadowcroft visitation may have occurred even earlier than 16,750 cal BP. It should be noted, however, that this date as well as a second one (21,000 cal BP) not on cut bark were both obtained from very small diluted samples and both are non-AMS assays with high standard deviations.

The lithic artifact assemblage associated with the earliest Meadowcroft populations is relatively small (ca. 700 specimens) but sufficient to characterize the industry. The Meadowcroft lithic debitage sample reflects secondary and tertiary core reduction and biface thinning from late-stage manufacture as well as the refurbishing of finished implements. The essentially curated tool kit notably includes an unfluted lanceolate bifacial point (the Miller point), and small prismatic to triangular (in cross section) blades struck from small prepared cores. Additionally, bone, wood, and plant fiber artifacts were also recovered from the site's pre-Clovis levels. These include plaited basketry, a bone punch, bone awl fragments, and a bipointed wooden tool, all apparently made by generalized foragers who exploited white-tailed deer (*Odocoileus* sp.) and smaller game along with hickory nuts (*Carya* sp.), walnuts (*Juglans* sp.), and hackberries (*Celtis* sp.), during the predominately short-term fall visits.

Sites and Chronology

The publication of the initial series of radiocarbon dates from Meadowcroft in the mid- to late 1970s, arguably when the Clovis First paradigm was at its zenith, constituted the first serious challenge to the Clovis First paradigm and was immediately met with acute skepticism and withering criticism. The intervening years, however, have witnessed the gradual unraveling of Clovis First in the face of mounting evidence to the contrary, both in the form of newly discovered Clovis contemporaries and/or pre-Clovis sites (which as of this writing number at least 35) and more subtle strains of evidence marshaled through advances in analytical techniques, multidisciplinary research initiatives, and innovative approaches. Molecular genetics, bioanthropological research, and historical linguistics, for example, have been enlisted in

the search for the points of departure for the early colonizers of the Americas. Unfortunately, although a northeast Asian origin is virtually universally confirmed, a geographically and genetically specific homeland/population cannot be specified. Moreover, continued archaeological research and refinements in historical geology, historical glaciology, and geomorphology have permitted a better understanding of prior population movements through the Russian Arctic and Siberia and an exploration of their implications for human subsistence and adaptability as well as the timing and route(s) of entry. Freedom from the strictures of received wisdom has also permitted the consideration of factors and approaches which might have previously been ruled out, such as the possibility of coastal (or even maritime) routes of entry to the Americas.

Pre-Clovis Sites

Perhaps the most important development has been the archaeological discovery of a growing number of far-flung localities in North and South America. These include sites which are clearly older than the Clovis horizon and/or penecontemporaneous and, hence, unrelated in any descendent way. Among the older sites is Cactus Hill in Virginia, a stratified, multicomponent, open site situated in an approximately 1.8 m thick aeolian dune deposit adjacent to the Nottoway River on the interior Coastal Plain of Virginia. The site was investigated by two independent groups, one directed by J. McAvoy (McAvoy et al. 2000; McPhail and Mcavoy 2008) and the other by M. Johnson (2012, 2013).

The occupational sequence at Cactus Hill is roughly confined to the upper 1 m of the site's dune deposit, but, like Meadowcroft, it extends from before Clovis times to the Historic period. In several sections of the site, a Clovis occupation has been identified beneath which lies a thinly, but clearly separated pre-Clovis component. The Clovis occupation is dated to ca. 13,300–12, 370 cal BP on the basis of firepit-derived charcoal. The pre-Clovis component has a series of radiocarbon and complementary OSL determinations. Notable are dates of 18,530–18,080 cal BP from a probable hearth and 21,930–18,490 cal BP from a charcoal concentration beneath a lithic tool cluster. A second date of 20,610–20,230 cal BP appears to confirm the other dates as do the OSL assays. Collectively, the data suggest one or more earlier than Clovis occupations dating ca. 20,000 cal BP.

Lithic analysis of the approximately 70 flaked stone tools from the pre-Clovis component (s) reflects a core and blade technology with two different kinds of small cores (conical platform cores with and without faceting and thick, chopper-like cores). The locally obtained quartzite cores were flaked with soft stone hammers or hardwood billets thought to have been prepared elsewhere then brought to the site for blade or blade-flake production. Also represented are at least two thin subtriangular to lanceolate unfluted bifaces. The excavators suggest that the blade and biface technology was employed by generalized foragers, not specialized big-game hunters. Additionally, the resemblance of the early Cactus Hill toolkit to its counterpart at Meadowcroft is readily apparent in all but raw material choices.

Interestingly, a generally similar toolkit with small prismatic blades, polyhedral blade cores, and unfluted lanceolate to triangular projectile points has been reported from Oyster Cove, Miles Point, and Cators Cove in the Chesapeake Bay region (Lowery 2007, 2010; Lowery and Wah 2011). At Miles Point, luminescence and radiocarbon dates suggest an age greater than 25,600 cal. BP, while Oyster Cove has yielded a date of 30,000 cal. BP. Though this toolkit *is* consistent with those recovered from lower and middle Stratum IIa at Meadowcroft and the deeper horizons at Cactus Hill, unresolved questions remain about the antiquity and geoarchaeological contexts of these materials in the Chesapeake region.

Although a uniform consensus exists for none of them, several other sites in North America are often cited as older than Clovis: Paisley Five Mile Point Caves in Oregon, Page-Ladson in Florida, the Schaefer and Hebior sites in Wisconsin, and the Deborah L. Friedkin and nearby Gault localities in central Texas.

The Paisley Five Mile Point Caves, which were initially investigated in the late 1930s, are a

complex of eight closed loci in south-central Oregon that were carved by wave action from basalts, volcanic tuffs, and breccias. Research at Paisley Five Mile Point Cave 5 (Jenkins 2007) has yielded durable and perishable artifacts, cultural features, late Pleistocene faunal remains, and putative human coprolites in apparent association within deeply buried stratigraphic contexts. Seven of the coprolites have been directly dated by radiocarbon assay, yielding ages ranging from 14,860–14,140 cal BP to 12,720–12,540 cal BP. Five of the dated coprolites have yielded human DNA and human protein residue and are often cited as among the oldest directly assayed evidences of a human presence in North America. Despite fanciful efforts to challenge the anthropogenic origin of the coprolites, many scholars accept these materials as demonstrating a pre-Clovis presence in the Pacific Northwest.

Page-Ladson is a sinkhole in the submerged bed of the Aucilla River in the Big Bend area of Florida (Dunbar 2006). Excavations in the deepest levels at this locus have produced lithic debitage, at least one unequivocal uniface, and apparent anthropogenically modified bones and ivory in apparent association with late Pleistocene megafauna including mammoth (*Mammuthus primigenius*), mastodon (*Mammut americanum*), horse (*Equus* sp.), ground sloth (*Megalonyx* sp.), and paleo-llama (*Llama glama glama*). A series of radiocarbon dates from these levels range from 16,360–15,100 cal BP to 13,770–13,440 cal BP. Limited re-excavations at Page-Ladsen have confirmed the original age assessments and suggest that Native Americans had arrived in northern Florida by ca. 14,400 cal. BP (Halligan et al. 2016).

More or less contemporaneous are a few sites that have been ascribed to the Chesrow complex, defined on the basis of 35 localities west of Lake Michigan in southeastern Wisconsin (Overstreet 2005). The Chesrow Complex includes both habitation and mammal kill/processing localities. The Chesrow artifact suite as derived from numerous sites includes unfluted lanceolate to basally thinned concave base points, other weakly stemmed points, bifaces, cores, utilized flakes, and hammer stones made largely from locally available quartzite cobbles. Two of the kill/processing sites, Schaefer and Hebior, have produced radiocarbon determinations from alleged associations with artifacts and extinct fauna. Schaefer yielded 15 dates ranging from as early as 15,150–14,630 cal BP to as late as 14,630–14,030 cal BP. Hebior yielded three dates ranging from as early as 15,170–14,670 cal BP to as late as 15,040–14,270 cal BP. At both sites, the principal associated fauna is mammoth (*Mammuthus jeffersoni*). Two additional Chesrow Complex sites, Mud Lake and Penske, have also yielded apparently butchered mammoths but without artifact associations. Mud Lake yielded four dates ranging from 16,520–16,100 cal BP to 16,380–15,950 cal BP, and Penske produced two dates of 16,490–16,070 cal BP and 16,420–16,010 cal BP.

Debra L. Friedkin and Gault are deeply stratified open sites in central Texas on the alluvial flood plain of Buttermilk Creek, a tributary stream in the Lower Brazos–Little Brazos watershed (Waters et al. 2011). Separated by less than 250 m, it is probable that both sites are part of the same very extensive series of seasonal residential occupations. Deep excavations at these localities have yielded long occupational sequences which include Late Prehistoric; Late, Middle, and Early Archaic manifestations; and the entire Paleoindian sequence, notably including well-defined (and in the case of Gault, very large) Clovis components. Beneath the Clovis layers at both sites is an extensive manifestation that is older than Clovis. At Friedkin, more than 15,000 artifacts have been recovered from the pre-Clovis levels, a total that includes 12 bifaces, 23 utilized flakes, 19 whole or fragmentary blade or blade flakes, gravers, at least one core, and one piece of polished hematite. The bifaces include unfluted lanceolate forms and exhibit varying thicknesses. A generally similar assemblage was recovered form Gault, specifically including fragments of two very small, expanding stem unfluted projectile points and at least one unfluted lanceolate biface. Gault also yielded a pre-Clovis stone pavement which may be part of an anthropogenically created dwelling or structure floor.

Optically stimulated luminescence dates suggest that the pre-Clovis occupation at Debra L. Friedkin ranges 15,500–13,200 cal BP, with a

similar estimate for Gault. It should be stressed that the Clovis occupation at Gault is far and away the most extensive ever recorded in North America. Stretching over a minimum of 12 ha, the Clovis component at Gault has produced more than 600,000 Clovis-age lithic artifacts from excavations covering less than 3% of the site's total surface area. Virtually all of the lithic artifacts recovered from both sites derive from extensive local outcrops of Edwards Plateau chert, which appears to have been a major attraction to populations visiting both sites throughout their occupational trajectories. Interestingly, the pre-Clovis technology at both sites shares certain attributes not only with later Clovis-age materials, but also with the pre-Clovis technology exhibited at such far-flung localities as the Chesrow Complex sites, Meadowcroft Rockshelter, and Cactus Hill. It is also significant that the excavators believe that the Clovis occupations at Gault and Debra L. Friedkin are probably both longer term and suggest a more broadly based subsistence lifestyle than that posited for this time period by the Clovis First paradigm.

Finally, recent excavations at Huaca Prieta, Peru, have revealed an intermittent human presence at around 15,000–8,000 cal. BP, well before the celebrated multistage mound was erected at this locality (Dillehay et al. 2017). Once again, the lithic tool kit is based on minimally worked unifaces, and the recovered dietary elements suggest the broad-spectrum exploitation of multiple environmental niches.

Clovis Contemporaries: Diversity and Dissimilarity from Clovis

As damaging as the evidence from the pre-Clovis sites summarized above is to the integrity of the Clovis First model, data from penecontemporaneous sites and/or complexes to which Clovis cannot possibly be ancestral are equally compelling. As with pre-Clovis manifestations, a significant number of sites, site complexes, and tool industries that have been identified across the length and breadth of the Americas have yielded bona fide artifacts and tool kits reflecting lifestyles that are sharply at variance with the putatively typical Clovis patterns. In far western North America, such phenomena notably include the Western Stemmed Tradition (WST) sites in the Great Basin and immediately contiguous areas (Beck and Jones 2010, 2013). Noteworthy among the WST sites are Smith Creek Cave in Nevada (with its Mt. Moriah points, gravers, and unifaces), Danger Cave in Utah, Connley Cave #5 in Oregon, Cooper's Ferry on the lower Salmon River in Idaho, Clarks Flat on the western flank of the Sierra Nevada Mountains in California, and Dietz in Oregon. While the deepest and oldest dates at several of these localities have been challenged and claims have been made that Clovis pre-dates the WST, it is generally accorded that in technological and behavioral terms these sites significantly differ from and are fundamentally unrelated to Clovis.

Far to the north at the eastern end of the Bering Platform are the central Alaskan sites of the Nenana complex: Dry Creek, Walker Road, Mock Creek, and Panguingue Creek in the Nenana Valley; Owl Ridge in the neighboring Teklanika Valley; and penecontemporaneous localities like Broken Mammoth, Swan Point, and Mead in the Tanana Valley (Goebel and Buvit 2011; Potter et al. 2013; Powers and Hoffecker 1989). Excavations at all of these open sites have produced generally similar lithic assemblages that include Chindadn points (an unfluted lanceolate to sub-triangular to teardropped form) and high frequencies of end and side unifaces (or scrapers), other unifacial and bifacial forms, a few true burins, and extensive debitage. Also present at most sites are small to medium-sized blades, blade cores, and tools made on blades (Powers and Hoffecker 1989). Once thought to represent a potential ancestor to Clovis, the Nenana complex is now viewed as a Clovis contemporary, dating to as early as 13,420–12,900 ca. BP at Walker Road and 13,498–13,305 at Dry Creek, with presently unpublished data from Swan Point suggesting that its lowermost cultural zone may be several 100 years older. Though sharing some broadly similar technological attributes with Clovis, Nenana is clearly not a descendant complex.

Farthest afield and, not surprisingly, evidencing the least technological or behavioral

resemblance to Clovis are a number of South American sites whose ages are either clearly earlier or broadly contemporary with Clovis. These include Lapa do Boquete, Lapa dos Bichos, and Grande Abrigo de Santana do Riacho in Brazil; Fell's Cave, Tagua-Tagua, Quebrada Santa Julia, and Quebrada Jaguay in Chile; Tibitó in Columbia; Cerro Tres Tetas, Cueva Casa del Minero, and Piedra Museo in Argentina; and Taima-Taima in Venezuela. Most of these sites have yielded undiagnostic flake tools as well as a minority of bifacial elements. A few, like Fell's Cave and Piedra Museo, have produced distinctive Fish Tail points once thought to be Clovis derivatives. Though many of these sites are only partially reported and few have multiple, internally consistent chronometric ages, the inescapable fact remains that their lithic industries are quite different from Clovis (or, indeed, any other North American industries) and are clearly not descended from them. Though this elemental lack of technical relationships has long been cited by South American archaeologists, it has been casually dismissed or ignored by some North American scholars.

Efforts to dismiss many of the early South American sites (including Monte Verde) are often centered on the nature of the associated lithic toolkits. Many of the South American sites lack typologically standardized bifaces and are, instead, focused on superficially simple, seemingly ad hoc unifacial technology. This unifacial technology is often derided (especially by North Americans) as "primitive" or "crude" and the unifacial toolkits recovered from some sites have even been attributed to nonhuman artificers in the form of capuchin monkeys!

Discussion

Just as the Clovis First model appeared to be consistent with and thereby supported by the extant linguistic and biological data of the 1950s–1970s, so also now does the pre-Clovis paradigm appear to be corroborated, however imperfectly, by more modern data from these same disciplines. Although space precludes in-depth discussion of recent genetic, bioanthropological, and linguistic scholarly efforts to address or establish the timing of the arrival(s) of the first humans into the Americas, suffice to note that virtually all of the available genetic, morphological, dental, and linguistic data continue to consistently and overwhelmingly point to an East Asian origin for Native Americans. Despite this fundamental consensus, however, some scholars suggest that at least one of the colonizing lineages (i.e., the X haplogroup) may derive from Iberia, not Siberia, while others advance the possibility of a Sub-Saharan African homeland for some native South Americans.

Any consensus on the number and/or timing of population pulses into the Americas based on nonarchaeological evidence is far more tenuous. Some geneticists and linguists favor a single movement, while others advocate two, three, or more population spreads. Some suggest an entry before the Last Glacial Maximum (LGM) now fixed between ca. 20,000–19,000 BP and 16,500 BP, others maintain a post-LGM entry, and others still postulate multiple movements before and after the LGM, occasionally with possibility of failed migrations. Likewise, various models have been offered to simulate rapid population expansion, slower spreading rates, and even very slow movements north to south. None of these models has achieved general or even limited acceptance, and the present state of knowledge unfortunately does not appear to permit the definitive establishment of a chronology for either the first or subsequent entradas. Indeed, Meltzer (2009:133) may well be correct that the ephemeral signature of the very first colonists on the American landscape will never be found.

If there is considerable disagreement over the timing and/or number of separate entradas into the Americas based on genetic or linguistic data, there is perhaps even greater dispute over the route or routes of entry. Some authorities still support the traditionally recognized entry route through the unglaciated interior of Beringia into the unglaciated Bering Refugium and thence down the ice-free corridor. In order to explain a very early human presence in archaeological localities situated over 5,000 km to the south – and, in the

case of Monte Verde in southern Chile, over 15,000 km to the south – a decades-old coastal migration hypothesis has been resurrected by recent scholars. Initially advanced by Simon Fraser University archaeologist K. Fladmark (1979), the notion that humans moved rapidly along the Siberian coasts, thence along the southern margins of Beringia and down the Pacific Coast to the northwestern United States and points south, has long been endorsed by archaeologists A. Bryan (1980, 1988), R. Gruhn (1994), and J. Dixon (1999), among others, and has been promoted most-recently by University of Oregon archaeologist J. Erlandson (2013) and his colleagues (2007). This postulated movement is thought to have involved both limited pedestrian traverse and the extensive use of watercraft.

Several variations on the theme of coastal migration have also been proposed. Archaeologist D. Anderson of the University of Tennessee, for example, has suggested that migration into interior North America first involved a southward coastal movement along the southern margins of Beringia to the tip of Baja California, followed by either a waterborne journey across a presumably narrow portion of the Gulf of California to mainland Mexico or a northward pedestrian movement up the east coast of Baja to the mouth of the Colorado River (Anderson 2013; Anderson et al. 2013). In either case, subsequent migration into different portions of the North American interior could have been facilitated. Alternatively, it has also been proposed that the coastal migration proceeded as far south as the Isthmus of Panama, which was then crossed at its narrowest point, followed by a northward movement along the Texas Gulf Coast and a bifurcation east to present-day Florida or northward through the Mississippi Valley. Of course, there is a distinct possibility that any combination of these routes could have been used simultaneously or sequentially by different pulses of colonists.

Perhaps the most controversial colonization scenario yet offered is the trans-Atlantic hypothesis championed by Stanford and Bradley (2012), which posits that maritime-adapted Solutreans emanating out of the Atlantic coast of southern Europe and traversing the North Atlantic in umiak-style watercraft. Upon arriving in the Americas, they are speculated to have introduced elements of Solutrean technology which ultimately gave rise to Clovis in the American Southeast. Stanford and Bradley cite the occurrence of the X haplogroup in Western Europe as well as a claimed series of congruencies between Solutrean and later Clovis technology, which they believe cannot be coincidental or reflect convergent evolution. They also cite very recent excavations on the mid-Atlantic coast as well as a series of offshore and terrestrial artifact recoveries of putative Solutrean implements to buttress their claims. Furthermore, to fill the chronological hiatus between Solutrean and Clovis, as currently dated, Stanford and Bradley pose Meadowcroft and Cactus Hill as transitional industries. No consensus has been achieved for this scenario to date, and initial scholarly reaction has ranged the gamut from scornful rejection to enthusiastic acceptance (cf., Straus et al. 2005; Meltzer 2009).

Whatever the plausibility of the trans-Atlantic theory, Stanford and Bradley have correctly stressed the fact, as did Dixon (1999), that scholars have collectively ignored the role of boats, water transport, and maritime adaptations in virtually all peopling scenarios for North America. Likewise, until recently, the inundated continental shelf on both the east and west coasts has never been systematically mapped or studied for the presence of early now inundated sites. This lacuna is now being addressed in both the Gulf of Mexico (Hemmings and Adovasio 2014), along various points of the Atlantic seaboard (Bailey et al. 2017), in the Gulf of California (Gusick and Davis 2010), and along the Pacific coast (Mackie et al. 2013).

Despite a sometimes-profound lack of resolution to the various issues surrounding the peopling of the Americas, however, several aspects of the debate that were once rejected out of hand by the scholars of the 1960s and 1970s have achieved widespread acceptance by the scholarly community. Based on Monte Verde *alone*, it is clear that humans entered the Americas well before the appearance and proliferation of Clovis technology. Furthermore, when other early sites and site complexes – such as Meadowcroft, Cactus Hill, Huaca Prieta, the Buttermilk Creek Complex, the Chesrow Complex, the Paisley Five Mile Point

Caves, and Page-Ladson – are considered along with penecontemporaneous sites/complexes like Nenana, the WST, and the flake-oriented industries of South America, the case for an earlier-than-Clovis presence is overwhelming. The diversity of the tool kits and attendant lifestyles at many of these sites points toward multiple movements by different groups at different times via different routes from East Asia.

Pereira, Edithe

Vera Guapindaia
MCTI/Museu Paraense Emílio Goeldi, Belém, Pará, Brazil

Basic Biographical Information

Edithe Pereira is a Brazilian researcher and archaeologist at the Emilio Goeldi Museum. She was born in the city of Belém, in the state of Pará, which is located in the Amazon region. She graduated from the Federal University of Pará in 1982 with a degree in history and began her career in archaeology in 1983, as a trainee at the Goeldi Museum under the supervision of Dr. Mário Simões. In 1988, Edithe Pereira joined the research framework of this institution, and in the same year, she started a master course in history at the Federal University of Pernambuco, intending to study Amazon ceramics. Instead, she was drawn to the research being done in Piauí by Dr. Niéde Guidon and her team, on what was what to become her greatest interest: rock art. Under the guidance of Dr. Anne-Marie Pessis, she wrote *As Gravuras e Pinturas Rupestres no Pará*, *Maranhão e Tocantins*: *Estado atual do Conhecimento e Perspectivas*, obtaining a master's degree in 1990. She then earned her Ph.D. at the University of Valencia, Spain, in 1996, with a thesis entitled *Las Pinturas y los Grabados Rupestres del Noroeste de Pará – Amazônia – Brasil*, directed by Prof. Dr. Valentín Villaverde Bonilla. As a dedicated researcher, Edithe Pereira has made rock art in the Amazon a lifelong project and has coordinated projects that include Survey of Sites in the Lower Amazon Rupestres Records (1990–1993), Rock Art and Archaeological Context in the Lower Region/Middle Araguaia (1999–2000), Arraias Stone to the Cadena Lajedo – the Characterization of Rock Carvings in Southern Pará (2000–2006), Rock Art of Monte Alegre – Dissemination and Memory of Archaeological Heritage (2012–2014), Rock Art and Archaeological Context in the Caves of Rurópolis (2012–2014), and the Pre-Colonial Occupation of Monte Alegre (2012–2014). She has also coordinated projects pertaining to contract archaeology, including the preventive archaeology program in the area of Serra do Sossego (2001–2006) and the archaeological survey in the area of the Belo Monte hydroelectric (1999–2000). Recently, Edithe Pereira began acting in the area of archaeological tourism, in partnership with the Instituto do Patrimônio Histórico e Artistico Nacional (IPHAN), on a pioneering project that aimed for the musealization of archaeological sites in the Amazon. She has organized archaeological tourism events; among these are the first and second Debate Forum in Archaeology and Tourism in the Amazon in 2005 and 2008, respectively, as well as the Symposium on Tourism, Archaeology of Research and Planning Methodologies (2008), and the International Tourism Workshop on Archaeological and Heritage Management (2009). The result of her involvement with this issue culminated in the book, *Turismo e Gestão do Patrimônio Arqueológico*, edited together with Silvio Figueiredo and Marcia Bezerra and released in 2012.

In 2016, archaeological research in the region of Carajás, southeast of Pará, coordinated by Marcos Pereira Magalhães revealed the existence of ancient paintings in a cave. It is the first site with rock art in this region, and the study of the paintings was by Edithe Pereira.

Also, since 2016, she has been part of an extension project called "Arqueologia nas escolas – histórias da Amazônia," whose objective is to disseminate the knowledge produced by archaeological research in the regions of Monte Alegre and Santarém, in Pará, through the elaboration of textbooks to the purpose of valorizing the Brazilian archaeological heritage and the history of the different peoples in the Amazon. As a curator, Edithe Pereira was responsible for the exhibitions "Visões – arte rupestre de Monte Alegre" (2013–2015) and "Origens – a Amazônia cultivada" (2016 until today), the latter in partnership with Cristiana Barreto. Another important project that has been carried out, as a productivity fellow of the Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq) (2017), is the study of the Protásio Frikel

collection resulting from its research in the Amazon in the 1950s and still unpublished.

Major Accomplishments

Edithe Pereira has contributed decisively to Amazonian archaeology, particularly in relation to her dedicated research on rock art. In the late 1980s when her history as an eminent researcher began, the landscape of rock art studies on Amazon was negligible compared to ceramic studies. All reconstructions of prehistoric occupation of the Amazon hitherto considered the occupation of the potter to be primary. To cope with this approach, Pereira's research associates a detailed survey of source tales, spatial distribution, visual documentation, and systematic analysis of rock motifs. From the results of this competent and meticulous work emerged the strong potential that studies of rock art in the Amazon have as another important area of knowledge in the reconstruction of the prehistoric Amazon. The bibliographic record on the subject deserves highlights: (1) the article "Testimony in Stone: Rock Art in the Amazon" (2001), which provides a summary of research conducted on the Amazon so far; (2) the book *Arte Rupestre na Amazônia – Pará* (2003), which finds, describes, and classifies information about each site and addresses issues such as the diversity of Amazon rock art and the problems of dating and archaeological context (it also sounds an alert on the issue of preservation of these sites, and the Academy of History Paulistana gave this book the CLIO award of History (2005)); (3) the book *Petróglifos Sul-Americanos* of Koch-Grünberg (2010), whose translation into Portuguese was organized by Edithe Pereira; and (4) the articles "Historia de la investigación sobre el arte rupestre en la Amazonía brasileña" (2006) and "Histoire, territorialité diversité et dans l'art de l'rock Amazonie brésilienne" (2011).

In 2008, Pereira Edithe coordinated the First International Meeting of Archaeology Amazon, based in Belém do Pará in an embodiment of the Goeldi Museum, in partnership with the IPHAN and the State Secretary of Culture for the State of Pará. This event fostered discussion on archaeological research conducted in the Amazon over the past 20 years, discussing topics related to the ancient settlement of this region, coastal occupations, domestication of plants, climate change, expanding linguistic, social complexity in ancient Amazonia, historical archaeology, transformations in the landscape, paleogenetic paleodemography, art and archaeology in the pre-colonial Amazon, and heritage education.

The book *Arqueologia Amazônica* (2010), co-edited by Edithe Pereira and Vera Guapindaia, presents the outcome of this meeting in two volumes that demonstrate the undeniable growth of different theoretical and methodological approaches in the study of prehistory Amazon (Whitehead 2011). Edithe Pereira continues to undertake her career as a researcher, producing knowledge that resulted in the recent book publication of *A Arte Rupestre de Monte Alegre* (2012). As the fruit of her research in Monte Alegre and aiming at the formation of new generations, she has published a children's book titled *Itaí – A carinha pintada* (2012), authored by Juraci Siqueira and illustrated by Mario Baratta, and has produced a documentary about the rock art of Monte Alegre (2012). Edithe Pereira is also a talented photographer taking most of the photos contained in her books and having published a book of photographs titled *Poemas deMiriti*, with Luiz Carlos França's poetry.

In the period from 2012 to 2015, he carried out research in the region of Rurópolis, in the southwest of the state of Pará, where he documented, studied, and published information and analysis on various sites including Cave of Hands – an unprecedented case in South American archaeology. Paintings and rock engravings in an aphotic zone in the deep interior of the cave.

Pérez Gollán, José Antonio

Javier Nastri
CONICET, Depto. de Cs. Nat. y Antropológicas + Fundación Azara, Universidad Maimónides/ Universidad de Buenos Aires, Buenos Aires, CABA, Argentina

Basic Biographical Information

Jose Antonio Pérez Gollán (1937–2014) was a prominent Argentinean archaeologist who has made a main contribution to the archaeology of the southern Andes. Born in the city of Córdoba, Pérez Gollán was educated in history at the National University of Córdoba, earning a B.A. in History in 1965 with a thesis on *Peopling Patterns of Northwestern Argentina*. That same year, he became a fellow of the newly created National Council of Scientific and Technical Research (CONICET), and 2 years later, he became a teaching assistant in anthropology at the National University of La Plata. In 1969 he became a researcher at CONICET, and in 1971 he was appointed professor at the National University of Córdoba.

In 1977 Pérez Gollán obtained a doctoral degree from the National University of Cordoba with a thesis entitled *Analysis of Archaeological Ceramics at the Site of Ciénaga Grande (Tumbaya Department, Jujuy Province)*. Immediately after this, he went into exile in Mexico because of the dangerous situation generated by the military dictatorship installed in Argentina in March 1976. In 1979, Perez Gollán was appointed professor and chair of Andean Ethnohistory at the National School of Anthropology and History and researcher of the National Institute of Anthropology and History, Mexico. Once constitutional order in Argentina was restored in 1983, he returned home to Argentina in 1987 and was reinstated and promoted at CONICET. In the same year, he became director of the Ethnographic Museum of the University of Buenos Aires. In 2005 he left that position to assume the direction of the National Historical Museum, where he served until 2013.

Perez Gollán has received throughout his career many honors, such as the First Prize (in collaboration) to the Regional Scientific Production (Central Zone), 1966–1967 of the Secretary of Culture of the Nation (Argentina); the Prize for Scientific and Technological Research of the Secretary of Science and Technology of the University of Buenos Aires (three times, in 1992, 1993, and 1994); the Critics Award 2004 of the Argentinean Association of Art Critics; the Marta Wegier Prize in 2005; the Konex Award 2006; and the Merit Diploma and Gratia Artis Award 2012 of the National Academy of Arts (Argentina).

Major Accomplishments

Pérez Gollán undertook his first archaeological experiences as a student at sites in the province of Córdoba, Argentina. From excavations in Los Molinos, he obtained the first radiocarbon dating of the province. Later he devoted his efforts to study of the formative period in the Humahuaca

Valley, in northwestern Argentina, developing a chronology of "La Isla" pottery, through cross-referencing information from sites in Jujuy with evidence from mortuary contexts of San Pedro de Atacama in northern Chile.

Between the late 1960s and early 1970s, Pérez Gollán published in collaboration with Alberto Rex González (Fig. 1) several works of synthesis on ceramic times in northwestern Argentina. One of them, *Indigenous Argentina. Eve of the Conquest* (González and Pérez 1972), remains to date the most widespread book on Argentine pre-Hispanic past, widely trespassing the boundaries of academia.

In the early 1970s, Pérez Gollán opened up new areas of research in partnership with his colleague and friend Osvaldo Heredia, another of González's disciples from the University of Córdoba. Together, these two investigated the little known area of Cafayate, in Salta, and then Ambato Valley, in the province of Catamarca. In the latter area, they made a transcendent discovery in the history of archaeological research in Argentina: the site of La Rinconada, also known as "Iglesia de los Indios," is the first known ceremonial center of the La Aguada culture (see Pérez Gollán et al. 1997). This archaeological culture had been defined by González a decade before, extending the proposals of Max Uhle, but until then no site assigned to that culture had been found. La Rinconada, subsequently investigated by González and then by Gordillo (see González 1998 for synthesis), provided extensive information on the middle period and on the social organization of sedentary populations in the northwest of Argentina.

In 1975, Pérez Gollán attended the famous meeting "Reunión de Teotihuacan," in which a group of Latin American archaeologists drafted the key document of the Marxist-inspired Latin American Social Archeology trend. During that trip, Pérez Gollán made contacts that would allow him to settle in Mexico 2 years later, in order to be safe from political persecution in Argentina by the military government. During his exile, he conducted several field projects and also began to investigate the history of archaeology, around the figure of Vere Gordon Childe. Pérez Gollán's (1981) book about Childe was the clearest demonstration of a theoretical commitment to leftist thinking by an Argentine archaeologist until that time. However, by then Pérez Gollán had begun to distance himself from the more orthodox and reductionist positions that flourished in the context of Latin American Social Archeology. His teaching work in Mexico put him in contact with Andean chronicles, in which he learned to investigate the symbolic meanings of pre-Columbian iconography. His interpretations of the iconography of Lafone Quevedo Disk (corresponding to the Aguada culture) are a milestone in terms of the development of an original form of hermeneutical studies of Andean indigenous material culture

Pérez Gollán, José Antonio, Fig. 1 José Pérez Gollán (at the right) with his master Alberto Rex González at the Ethnographic Museum of Buenos Aires in 1999. (Courtesy of Pérez Gollán)

Pérez Gollán, José Antonio, Fig. 2 Bronze plaque known as "Lafone Quevedo Disk," whose iconography was studied in detail by Pérez Gollán. (Taken from González 2007)

Pérez Gollán, José Antonio, Fig. 3 Facade of the Ethnographic Museum of the University of Buenos Aires. (Photo by Javier Nastri)

(Pérez Gollán 1986). On a similar vein, he produced a new interpretation of the artifacts known as "pleadings" (*suplicantes*): small stone sculptures of high artistic value, corresponding to the formative period of the Argentine Northwest (Pérez Gollán 2000) (Figs. 2 and 3).

During the 1990s, Pérez Gollán resumed fieldwork in Ambato, Argentina, with colleagues from the National University of Córdoba, revealing ceremonial and habitation sites of the Aguada culture. He conducted then a "rethinking" of that culture, proposing to redefine the middle period as the "Regional Integration Period." Questions like this gave a strong impetus to research on the topic, which crystallized even in specific conferences on the issue. After that, Pérez Gollán's research has focused on the study of the late period at Ambato Valley, about which very little is known until now.

In addition to his archaeological fieldwork, Pérez Gollán is widely recognized for his work as a director of major museums. He introduced modern standards of preservation and exhibition of collections, refurbishment of infrastructure, repatriation of remains, and publishing catalogues during his periods as director at both the Ethnographic Museum of the University of Buenos Aires (Fig. 3) and at the National History Museum of Argentina.

Periodization in Japanese Prehistoric Archaeology

Makoto Tomii
Centre for Cultural Heritage of Kyoto University, Kyoto, Japan

Introduction

It is possible to apply European periodization to Japanese history: prehistory, protohistory, Ancient, Medieval, Early Modern, and Modern. In this entry, I suggest that Ancient period is from 593 to 1192, Medieval from 1192 to 1573, Early Modern from 1573 to 1868, and Modern from 1868 onwards. The prehistoric period consists of the Paleolithic, *Jomon*, and *Yayoi* periods, and protohistory is virtually equal to the *Kofun* period. The Ancient period is composed of the *Asuka*, *Nara*, and *Heian* periods, and the Medieval period is composed of the *Kamakura* and *Muromachi* periods. The Early Modern period consists of the *Azuchi-Momoyama* and *Edo* periods. The name of a period from Ancient to Early Modern signifies the location of either the capital or the governmental office at that time.

The European periodization based upon the 3-age system is not suitable to the case of Japan. While the Paleolithic period in Japan had stone axes with ground edges, and the Stone Age is followed by the Iron Age, the Bronze Age is absent. Instead, pottery/ceramics can be used for marking boundaries in time scales, though certain changes in ceramics in the historical period do not necessarily correspond with an epoch-making event of history in cultural, political, or economical terms, other than in a few exceptional cases, such as the start of production of porcelain which occurred immediately after the dawn of *Edo* period. Especially after the introduction of kiln firing, in the middle of the *Kofun* period, the sequence of diagnostic pottery types can be a chronological measure that can mark off every one-fourth or one-fifth century. Even before kiln firing, in spite of its long duration over 14,000 years, pottery is effective in providing precise relative dating. This is because of the huge number of prehistoric sites excavated so far to produce the archaeological data, including pottery that is regarded as time sensitive. The period before the invention of pottery manufacturing is called the "Paleolithic," though it is sometimes alternatively called the "preceramic" period. In terms of periodization in archaeology, the following paragraphs focus on pre- and protohistory – the Paleolithic, *Jomon*, *Yayoi*, and *Kofun* periods.

Key Issues and Current Debates

Most archaeologists now assume that the first occupation in the Japanese archipelago can be traced back to around 30,000 BP, though they once accepted that this phenomenon could have happened even much earlier. Artifacts dated to about 30,000 BP are often called Middle Paleolithic, though they are not necessarily similar in form to artifacts from the European or Continental Middle Paleolithic.

The first discovery of Paleolithic stone tool, in 1949, was long after pottery in Jomon period was

recognized as the oldest ceramics in Japan. The most common kinds of stone are obsidian, sanukite, and flintlike silica shale, all of the three also common in Jomon and Yayoi periods. After two decades, the quantity of preceramic artifacts became sufficient to consider a sequence for the Japanese Paleolithic. During the 1970s, before the famous fabrication by Mr. Fujimura (SICPEMP 2003), Professor Sosuke Sugihara, who was one of the two leading scholars in Paleolithic studies, first proposed the subdivision of the Paleolithic into four stages: (1) axe tool, (2) blade tool, (3) point tool, and (4) microlithic. Professor Chosuke Serizawa, the other leading Paleolithic scholar, had pursued studies of the old Paleolithic, which would be comparable to the Early or Middle Paleolithic in the continent, for the latter half of his lifetime. He tried, on the one hand, to distinguish stone tools from eoliths by microscopic use-wear analysis that he introduced to Japanese archaeology and on the other, to pay attention to the different kinds of stone, particularly of chert.

The Paleolithic period is the age of the forager. There are dozens of examples of house structures from this period. However, they are considered to have been a beehive and to have functioned as temporary accommodation. The Paleolithic period ends with the appearance of pottery, and the Jomon period starts. However, the invention of pottery is now recognized to have happened within the last glacial period, rather than being the result of adaption to a post-Pleistocene environment. When Paleolithic stone tools are found with pottery, they are regarded as belonging to the Jomon period. This is one of the reasons why some archaeologists still use the term "preceramic."

The Jomon period is the time of fisher-hunter-gatherers with pottery, ranging from 15,000 to about 2500 BP. During the 1930s, the Jomon period was divided into five main stages according to the relative balance in numbers of pottery types in each stage: initial, early, middle, late, and final. By the 1960s, the incipient stage was added to the division as the first stage. Dr. Sugao Yamanouchi proposed the basic framework for this chronological division of the sequence of Jomon pottery. In some areas where the archaeological materials are rich, there are more than 60 subdivided periods of time, indicated by differences in pottery types. Jomon is originally the consolidated term, *Jo-mon*, for describing a decoration made by a cord-mark; *Jo* means a cord or a string, and *mon* means a figure or a pattern.

Between the final Paleolithic and the incipient Jomon, stone industries are not distinguished in practice by archaeologists; bifacial points or microblades are associated with potsherds in some cases, and not in other. However, at around 10,000 BP at the latest, a sedentary lifestyle was set up, indicated by pit-dwelling house structures and the appearance of the concept of a burial area, as well as by a broad spectrum of subsistence strategies suggested by storage pits, shell middens, saddle querns, and so forth. Such Jomon collectors often occupied a large area for their settlement, which would lead to a circular village. They produced a large number of objects and features, such as clay figurines, phallic stones, pottery embedment into the earth's surface, and stone circles, all of which show their religious customs and beliefs, though the meaning of this is too difficult for us to access.

The Jomon period ended with the establishment of the systematic cultivation of rice, and the Yayoi period began. Until the 1920s, rice cultivation was believed to have been introduced with metal use into Japan. However, domestication in itself now can be recognized in the Jomon period. In terms of animals, dogs must have been domesticated much earlier, based on the evidence of their burials. In terms of plants, various types of millet are thought to have been introduced by the late Jomon. As Dr. Yamanouchi's pioneer study (1925) pointed out, rice is also likely to have existed in the final Jomon period at the latest, as evidenced by rice impressions in the textile of, and on the surface of, pottery.

Yayoi is named after the type-site in Tokyo where the first Yayoi pottery was found in 1884. This pottery was recognized as different from Jomon pottery in textile and color. Until the 1930s, differences between the Jomon and Yayoi pottery were generally considered, by almost all

leading scholars including Ryuzo Torii and Kosaku Hamada, to have been due to the differences in the people who produced the respective pottery. By the 1940s, Dr. Yukio Kobayashi (1943) completed the framework of the relative dating by pottery in Japan. The Yayoi period, from the middle of the first millennium BCE to the early third century CE, is classified by the design of pottery into three main stages: early, middle, and late. Pottery of the beginning of the early Yayoi period can be distinguished from that of the Jomon period in many areas not only by the materials used but also by production technique.

The Yayoi period is also marked by the introduction of metal use. Although bronze did not replace stone as the main sharp-edged tool, it served as a ritual good from the early Yayoi period. Stone as a sharp-edged tool was almost fully replaced by iron by the late Yayoi period. Such metallurgy was diffused from the continent through the Korean peninsula, as was the new technology for manufacturing pottery.

Yayoi farmers conducted mixed farming with pigs and rice and often built a settlement enclosed by a causeway in which towers, storage buildings, and a shrine were accompanied by normal pit-dwelling houses. These settlements formed a large and complex network of information and exchange not only within the Japanese archipelago but also stretching to the Korean peninsula as indicated by the similarities in pottery, polished stone swords, house plans, and so forth. Moreover, the network was connected with the Chinese continent, as evidenced by imported prestige materials such as bronze mirrors.

Yayoi farmers were usually buried in a cemetery, and some of them were deliberately interred in a specific individual grave, within coffins made of wood or cist stone along with other grave goods such as beads, bracelets, swords, and imported mirror. These individual burials were sometimes surrounded by ditches of square shape in the early Yayoi and of circular shape in the late Yayoi. They strongly suggest the appearance of chiefdoms. By the end of the late Yayoi period, some of these delimited graves increased the volume of burial mounds into barrows, in several parts of Japanese main islands. This phenomenon might well point to the appearance of elites and the affiliation of them as well. When the area for mortuary ceremony attached to a barrow within the inside of the ditch, the barrow in turn became a Kofun tumulus.

The Kofun period, from the middle third century to the early seventh century, is characterized by the overwhelming vogue to construct tumuli and is divided into three stages: early, middle, and late. The difference between a Yayoi barrow and a Kofun tumulus is subtle. As for the barrow of elites, the mortuary ceremony area was enlarged, and the barrow took a keyhole shape. However, the normal individual burial did not change virtually. However, pottery at the beginning of the Kofun period, called "Furu" type, is easy to distinguish from Yayoi pottery because it has a distinctive feature in the profile of its rim. It also has a wider distribution in many areas. Thus, although there are a number of archaeological sites of this period without a tumulus, such as settlements and ritual sites, they can be dated by the Furu-type pottery. The early Kofun period is also defined as the advent of Haniwa, which was a large ceramic object of various shapes which was placed in line(s) on the surface of tumulus for external decoration. Some of the largest tumuli in the early Kofun period are located in the Kinki region. This fact may support the argument for Yamatai-koku, which was recorded as one of the supreme chiefdoms dominated by the queen named *Himiko* within the Japanese archipelago in the imperial chronicle of the *Wei* dynasty in ancient China and which is deeply rooted in the identity of modern-day Japanese people.

The middle Kofun period is identified by the introduction of *Sue* pottery, which was the first pottery to be fired in kilns in the history of ceramics in Japan. As for tumuli, the middle Kofun period is also distinguished by the introduction of specific grave goods, other than Sue pottery – a set of harness. This means that the horse was introduced at around this time. These innovations were due to the influence of an immigrant population from Korean peninsula.

The distinction between the middle Kofun period and the late Kofun is rather arbitrary, based on a gradual change in form of the various objects in material culture as well as in both the scale and shape of tumuli. The most important characteristic of the late Kofun period is the introduction of

Buddhism, dated to 552 or 538. Buddhism became popular with elites, who replaced the Kofun tumulus with a Buddhist temple, which was a different form of monument to their power. By the end of the sixth century, the emperor established his/her power at the pinnacle of hierarchical society in the main lands of Japan and constructed the capital in Asuka area, resulting in the birth of the state of Japan. In terms of archaeological objects, the latter half of the late Kofun period, or Asuka period, is characterized by the appearance of roof tiles engendered by the adoption of Buddhism, though roof tiles were only used in Buddhist temples and in the capital at this time.

The age from the late Yayoi period to the end of the Kofun period is so called the time of the "state formation process." This process has been well studied by many scholars including historians, along with the everlasting controversy in the identification of the location of Yamatai-koku (Saeki 2006, as an example). In terms of archaeological contributions to the study, barrows and tumuli have long been intensively researched by many archaeologists, for example, Professor Yoshiro Kondo (1983, as an example) and Professor Hiroshi Tsude (2005, as an example), while the long history of thorough investigation of not only other features and monuments, including causewayed settlements, shrines, and temples, but also artifacts such as bronze mirrors, iron tools, and *Sue* pottery should not be underestimated.

Permafrost Digging

Vladimir V. Pitulko
Paleolithic Department, Institute for the History of Material Culture, Russian Academy of Sciences, St. Petersburg, Russia

State of Knowledge and Current Debates

Introduction

For archaeological sites and materials, especially the most ancient ones, permafrost conditions have a dualistic character. On the one hand, they promote preservation of non-durable artifacts that would have been seriously damaged or completely destroyed outside the permafrost context. Temperatures below 0 °C, fluctuating little over time, and anaerobic conditions allow for preservation of various substances and organic remains, like biological materials from archaeological excavations, including aDNA and sedDNA (Hollesen et al. 2018).

However, even in permafrost conditions, artifacts may be destroyed as a result of the growth of subsurface ice and cryoturbation, due to mechanic (breaking and splitting) and biogeochemical impacts (Pitulko 2007). The latter has a special effect on preservation of artifacts made of osseous materials, archaeological wood, and other organic matter in cases when artifacts and other evidence of past human activities are located on the permafrost table and remain there long enough prior to the final transfer into permafrost. Biogeochemical processes, which we can generally classify as in situ chemical weathering complicated by microbial activity and root etching, are most active near the seasonally thawed layer base because the latter acts as a water table as well. Multiple repeating freezing/melting cycles unfavorably affect water-saturated artifacts. Nevertheless, in general, permafrost conditions are more favorable than harmful for artifact preservation.

On the other hand, permafrost conditions seriously limit the in situ artifact position in the cultural layer and this layer's integrity. Under certain conditions, they can promote fundamental transformation of the original contexts and even create secondary ones, which, after a while, would become frozen and might be mistakenly interpreted as the original context. Besides, frost deformation of deposits, or cryoturbation, causes errors in evaluating deposit chronometry (Pitulko and Pavlova 2016).

The abovementioned potential errors are most probable in areas where currently there is no permafrost, but it was well developed there in relatively recent times (Vandenberghe et al. 2014). Finally, permafrost conditions significantly obstruct archaeological excavations and, especially, site prospecting, because they limit the ability to lay out and excavate test pits. Cryogenic features of deposits containing the cultural layer of an archaeological site fully dictate the strategy and tactics of working there.

Archaeologists exploring the coastal zones of arctic Eurasia and North America (Friesen and Mason 2016) and Arctic islands (Pitulko and Makeyev 1991), including Greenland (Grønnow 1994), are typically most often involved with permafrost excavations. The culture-bearing deposits of such sites, though perennially frozen, have been in this condition since relatively recent times, as their age is less than 9000 years.

Under the conditions of continuous permafrost, difficulties in arranging excavations increase massively. Most frequently, accounts of such fieldwork say that when excavation reached the permafrost level, researchers stopped because it was impossible to work further, even though sterile levels had not been reached yet and cultural material continued down. Judging by descriptions, the limited excavations conducted by Mochanov (1977) at the Berelekh site in the early 1970s were exceptionally labor-consuming. Basic problems in such fieldwork are slow melting of the frozen cultural horizon, loss of the melted deposit volume, landslides, ability of thawed deposits to flow, and abundance of water causing drainage problem.

The most successful were extensive excavations performed in the continuous permafrost zone at the Zhokhov (Pitulko 2013; Pitulko et al. 2015) and the Yana sites (Pitulko et al. 2013). The experience excavating these sites formed a

specialized expertise (Pitulko 2007) presented below and preceded by necessary information on peculiarities of perennially frozen deposits.

Permafrost Basics

Permafrost, or perennially frozen ground, is the Earth material that remains below 0 °C for at least 2 years. Permafrost is characterized by humidity exceeding that of unfrozen/bound water under the given temperatures and ice that cements mineral particles and fills cavities, pores, and fissures in rocks. Frozen deposits are exceptionally varied (e.g., Romanovskiy 1993; Yershov 1998; French and Shur 2010). They include both dispersed deposits (debris, sand, clay, turf) and fissured weathered magmatic, metamorphous, and cemented sedimentary rocks. Ground (river, lake, sea, glacier) and underground (buried, wedge, injection, segregation, sheeted) ice and snow accumulations are considered monomineral rocks, while ice is recognized as a specific mineral (Yershov 1998: 11).

Areas of perennially frozen sediments form the *cryolithozone* defined as the Earth crust where all rocks have negative temperatures irrespective of the availability and phase of water in it. The cryolithozone consists of frozen, frosted, and chilled rocks (Romanovskiy 1993). By their existence in the frozen condition, all sediments and rocks are divided into diurnal, seasonally frozen, and perennially frozen, and they all form via lithosphere *cryogenesis*, one of the fundamental processes occurring repeatedly throughout the geological time.

Cryogenesis is defined as a complex of processes and phenomena in the upper lithosphere horizons, both in formed rocks of various age and/or composition and in accumulated sediments. These processes are determined by freezing and melting of rocks and sediments, by their chilling and heating, and by changes in pressure (Romanovskiy 1993). Thus, cryogenesis is a complex interplay of processes and phenomena whose development determines exogenetic dynamics, structural features of upper rock horizons, and the topography inside the cryolithozone. Perennial freezing of rocks and sediments determines their specific features – such as their cryogenic structure, i.e., the availability of subsurface ice and its distribution in rock masses.

Geographically, permafrost is classified as subaqueous, subglacial, and subaerial. The latter is the most widespread type and thus the most important for archaeological studies. In the Northern Hemisphere, permafrost underlies approximately 22.79×10^6 km^2 or 23.9% of the exposed land. It is a trans-zonal natural phenomenon spread in the Arctic and the moderate climatic belt within a few landscape zones. The largest permafrost areas are the Asian (~13×10^6 km^2) and the North American (~7.2×10^6 km^2); they spread from the shores of the Arctic Ocean far southward, deep into the continents (Fig. 1).

In Northern Eurasia, cryolithozone extends down to 45°N, while in the northern North America, its uneven southern boundary fluctuates between ~52°N and 56°N. The permafrost area in Eurasia is significantly larger than its North American areal. This difference between the continents and the differences in physical characteristics of permafrost conditions observed there are of a fundamental character due to their geological history, specifically, their glaciation history (Romanovskiy 1993: 13–23).

Subaerial permafrost is divided into two basic zones, northern (continuous) and southern (sporadic); they are separated by a transitional area of discontinuous permafrost. Continuous permafrost is located in the northern part of the Asian and North American permafrost areas. Perennially frozen sediment and rock in the continuous permafrost area in Northern Eurasia is tens to hundreds of meters thick; the known maximum thickness is about 1500 m. In the North American continent, frozen rocks are significantly thinner.

Based on long-term observations, it has been established that the typical mean annual temperature range for perennially frozen rocks is –(3 ÷ 9)°C in the area of their continuous spread. The lowest temperature of –(12 ÷ 14)°C is recorded on the coast of the Laptev Sea. In the southern area of sporadic permafrost, these values range within 0°÷(−2)°C. In the transition zone, where permafrost is discontinuous, mean annual temperatures of perennially frozen rocks vary from −1 °C to −3 °C.

In any part of the world, permafrost areas are most frequently sparsely populated and difficult to

Permafrost Digging, Fig. 1 Permafrost distribution in the Northern Hemisphere (**a**) and schematic vertical profile of the permafrost from North to South in Northern Eurasia (**b**) based on the NASA image (www.climate.nasa.gov)

access, with poorly developed infrastructure and, as a result, high logistical costs. Archaeological surveys in those areas are currently conducted with low intensity. However, in the nearest future, archaeological investigations in permafrost regions are expected to accelerate.

Formation of the Cryolithic Zone

Cryolithic zone formation is a long-term cyclic process, which results from complex interaction of primarily climatic factors, mainly (1) mean annual $t < 0$ °C; (2) cold winters with little snow, providing deep freezing of the rocks from the surface; and (3) short and/or cold summers, during which frozen deposits cannot completely thaw.

Significant cooling events that caused temporary spread of permafrost occurred many times throughout the Earth history. Paleogeographic events recorded within the depths of perennially frozen or completely thawed deposits reveal the genesis of perennially frozen formations and allow researchers to establish the connection of frozen deposit formation with paleoclimatic and

paleogeographic events. Studying such sequences is the subject of cryostratigraphy, an important instrument of Quaternary geology (French and Shur 2010) and geoarchaeology (see, e.g., Amirkhanov et al. 2009; Velichko et al. 1997; Pitulko et al. 2013; Todisco et al. 2009).

Besides glacial formations in Antarctic and Greenland, reliable traces of the latest planet-wide cryogenic event are found in Quaternary deposits. Over the last 2.5 Ma, four stages are distinguished in the cryolithic zone development (Romanovskiy 1993); they differ in length and in formation conditions. The first stage includes the Early and Middle Pleistocene; the second, the Late Pleistocene–Early Holocene; the third, the Middle Holocene; and the fourth, the Late Holocene. The oldest permafrost, which is quite rare, is known mostly in Northeast Siberia (Romanovskiy 1993; Yershov 1998); however, the younger the geological age of such deposits, the more obvious and various the evidence of cryogenesis that formed the modern cryolithic zone.

Archaeological record for human habitation in the permafrost regions largely coincides with the development of cryolithic zone during stages two, three, and four. On the geological time scale, it has several maxima that correspond to the cold events of the last cycle of the Quaternary glaciation, which includes the penultimate interglacial (~130,000–115,000 yrs. B.P., MIS 5e, Eemian), the last glaciation (~114,000–11,700 yrs. B.P., from MIS 5a-d to MIS 2, Last Glacial Period, or Weichselian), and the last interglacial (~11,700 yrs. B.P. to present, MIS 1, Holocene). The Last Glacial Period was structurally complex, represented by several large divergent events, three glaciation stages (MIS 5a-d, Early Weichselian; MIS 4, Middle Weichselian; MIS 2, Late Weichselian), separated by relative warmings. The last stage of the Weichselian glaciation (~28,000–19,000 years ago) was the coldest and is referred to as the Last Glacial Maximum, a period during which permafrost distribution reached its maximum (Velichko and Nechaev 1992; Vandenberghe et al. 2014).

The second stage in the cryolithic zone development (~130,000–8000 years ago) is characterized by especially severe geocryological conditions in a significant part of North Eurasia and North America. On the East European Plain, the cryogenesis evidence has been described as far south as 47–48° N; further to the East, the southern boundary of the cryolithic zone might have been shifted somewhat to the south (Romanovskiy 1993; Yershov 1998).

On the North American continent, permafrost formed only in the ice-free area in the northeast of the continent; its entire north portion was occupied by the Laurentide Ice Sheet (Wisconsin glaciation), with the maximum extent in its eastern part as far south as ~38° N (Stokes 2017), which implies only limited subglacial permafrost. Thus, in most permafrost areas of North America, conditions suitable for its formation emerged only in Holocene, after deglaciation. In contrast, in the iceless northwest region of the North American continent, permafrost-forming conditions similar to the Ice Complex deposits in East Siberia existed throughout the entire Pleistocene (Kanevskiy et al. 2011).

In Northern Eurasia, the magnitude of the Late Pleistocene glacial events (middle and later stages of the Weichselian glaciation) was smaller than those of the Middle Pleistocene glaciation and significantly smaller than the Wisconsin glaciation in North America. Throughout MIS 4 and MIS 2, there had been extremely favorable conditions within the entire ice-free North Eurasia for permafrost development; for the increase in the cryolithic zone extent, including the increase due to the freezing of arctic sea shelves, exposed by the sea level regression; for the increase in permafrost thickness; and for the development of multi-layered permafrost. The cryolithic zone extent in Pleistocene is believed to have exceeded the current permafrost range by approximately 20%.

In East Siberia, several generations of multi-layered permafrost formed (Romanovskiy 1993; Nikolskiy and Basilyan 2003; Schirrmeister et al. 2013; Saito et al. 2014). For the East European Plain, several horizons of paleocryogenesis have been described (Velichko 1973). During these roughly 120,000 years, cryogenic processes alternated: periods of permafrost growth were followed by periods of degradation, by partial or complete thawing of frozen deposits (Baranova

and Biske 1964; Kaplina 1981, 2009), by the development of thermokarst and other thermo-denudation processes observed in the stratigraphic records as erosive and thermoerosive unconformities, and by active permafrost growth. An abrupt intense cooling event, which took place in the entire Northern Hemisphere 8200 years ago due to the Laurentide Ice Sheet breakdown, should probably be considered the boundary between the second and the third stage of the cryolitozone development.

The third stage of the cryolitozone development dates to the Middle Holocene, in general to the timeframe of about 8000–5000 years ago. During this time, permafrost degradation occurred widely. The permafrost boundary shifted 1000–2000 km to the north; in the European part of the continent, it retracted to the Arctic Circle; in West Siberia it stopped along ~68° N and in East Siberia, along ~60° N (Romanovskiy 1993). By the end of the Holocene climatic optimum, frozen masses in the south had thawed completely, and to the north, permafrost had thawed from the surface, while the seasonal thawing depths increased. In some areas, isolated masses of relic permafrost remained; in the northern part of the cryolithic zone, lake thermokarst was actively developing. These processes continued the large-scale transformation of the topography and the landscape in Northeast Siberia called thermoplanation (Baranova and Biske 1964) that had started at the end of the second stage of the cryolithic zone development.

Finally, the fourth stage of the cryolithic zone development dates to the second half of the Holocene (from ~5000 years BP to the present). It is characterized by climatic and geocryologic conditions more severe than those of the previous stage. This caused aggradation of the permafrost and some shift of the cryolithic zone boundaries to the south. Areas previously freed from glaciers froze; secondary freezing took place in the previously thawed deposits that often crown the profiles of frozen deposits in the southern part of the northern geocryologic zone. In the northern part of the cryolithic zone, the growth of underground ices resumed, and the most recent generations of polygonal ice veins formed. Frozen sediments, which formed in Late Holocene, comprise the southern geocryologic zone, characterized by mostly discontinuous, massive-sporadic, and sporadic permafrost distribution.

Thus, the current distribution of perennially frozen rocks had formed (Fig. 1). However, it underwent noticeable transformations in the historic period, including after the scientific research of this natural phenomenon began.

Basic Types of Permafrost According to Freezing Conditions

By freezing conditions, frozen sediments are divided into epicryogenic and syncryogenic; however, thick polygenetic frozen sediments containing both epigenetic and syngenetic permafrost are most common. Epigenetic permafrost includes deposits of various composition, genesis, cryogenic structure, ice content, and age. The cryogenic age of these rocks, i.e., time of their transition to perennially frozen state, which has existed continuously to the present, varies from Early Pleistocene to Late Holocene. The geological age of epicryogenic rocks always exceeds their cryogenic age. The time lag between the formation of deposits and their transition to perennially frozen state can be hundreds, thousands, or millions of years.

Unlike epicryogenic formations, syncryogenic deposits are formed in the process of simultaneous accumulation of sediments and their freezing. Thus, the geological age of syncryogenic deposits approximately coincides with their cryogenic age. This difference is fundamental; however, equally important is the accumulation history of frozen sediment: if the epigenetic permafrost thickness grows due to the deepening of the perennially frozen base, the syncryogenic deposit thickness grows due to the upward migration of the permafrost table, as a portion of water-logged sediment at the bottom of the seasonally thawed layer (STL) freezes to the permafrost deposits. As a part of this process, ice belts of various thickness (ice *schlieren*) form due to separation of water from unconsolidated rocks that constitute STL and since the permafrost table acts as the impermeable layer.

Thus, the ability to distinguish epi- and syncryogenic deposits appears quite important for

investigating traces of former human activities (archaeological remains) within frozen deposits. Perennial frost conditions per se do not assume an unchanged primary archaeological context. For instance, cultural remains enclosed in epigenetic frozen deposits can often be redeposited, while archaeological materials within syngenetic frozen deposits are guaranteed to be in situ and should match, in both geological and geocryological age, the matrix sediments and be in agreement with their stratigraphic position.

Syncryogenic deposits are spread from the surface and associated only to accumulative forms of the relief. They always form on a frozen substrate, i.e., on epicryogenic perennially frozen sediments. By origin, they are mostly continental deposits, alluvial, lacustrine-alluvial, proluvial, aeolian, and glacial of different ages, from Early Pleistocene to Holocene. They form and exist in the cryolithic zone conditions, with higher ice content and specific cryogenic structure significantly dependent on the time of their formation. Such deposits are primarily subject to thermokarst and long-term thawing in the periods of climate warming, which results in their transformation into *taberal* deposits (perennially frozen deposits that experienced thawing – some completely thawed – having lost their cryogenic structure, as well as thawed and refrozen deposits as defined by Kaplina 1981). These processes are important factors of geoarchaeological research in the cryolithic zone.

Syncryogenic deposits are the most characteristic group of unconsolidated rocks in the cryolithic zone. By conditions of accumulation and primary diagenetic transformations when freezing, they are subdivided into subaqual, subglacial, and subaerial. The latter are most important archaeologically as they are most widespread and include deposits that became perennially frozen while the sediment accumulation surface was in contact with the air. Syngenetic freezing is most completely expressed in formation of floodplain, delta, shoal, slope (delivual and solifluctional), and aeolian deposits.

Such deposits often contain remains of plant root systems, organic interbeds, bone remains, and corpses of Pleistocene animals. They can also contain archaeological materials, both dispersed cultural remains and horizons of archaeological materials formed on the ancient day surface (faunal remains of human prey, artifacts and their production waste, trash, and other material traces of human activity). As the deposit thickness grows, such horizons turn into culture-bearing deposits generally referred to as "the cultural layer."

This is a slow process, during which the sediment is accumulated on the day surface and deposits of the lower part of the seasonally thawed layer turn to permafrost. The transition occurs not annually but intermittently (in rhythms), causing the syncryogenic sediments to often have clearly visible rhythmic structure, with various proportions of organic-mineral components and schlierens (subhorizontal interbeds) of almost pure ice. Therefore, the rhythmic (stratiform and lenticular) organization of cryogenic structures observed in frozen deposit sections is typical for syngenetically frozen deposits. It also testifies to in situ conditions of the materials.

As a rule, syngenetically frozen deposits consist of the finely grained fraction: they are pulverscent/silty/dust loess-like sediments (icy aleurites). In weakly lithified perennially frozen deposits of East Siberia, the volume share of ice can easily exceed 50 percent, changing zonally.

Extreme pulverescence typical for such deposits is due to the multiple repeating of freezing/melting cycles affecting sediment particles while they are located at the STL boundary. These are, basically, the clay particles which constitute the main frozen deposit component in the cryolithic zone.

It has been demonstrated experimentally that after only 50 freeze-thaw cycles, active dispersion and degradation of clay particles occur (Konishchev and Rogov 2008). The lowest number of such cycles, after which the finely dispersed varieties of STL sediments would turn into a syncryogenic frozen deposit, is estimated to be in the hundreds to thousands (Yershov 1998).

Cultural material in the STL boundary will be damaged by the same processes, as well as being actively weathered chemically and biologically, until it becomes permafrost. Examples of such impact are clearly seen on materials from the Yana site (Burshneva and Pitulko 2014).

Permafrost Digging, Fig. 2 (continued)

Fine-grained sediments are extremely favorable for the formation of various ice structures due to freezing from the surface. Ice participating in permafrost formation, in any of its varieties, can be both epigenetic and syngenetic. In frozen deposits, it is available in three basic forms: vein ice, pore ice, and segregation ice. Relative location of ice and sediment forms specific cryogenic textures that characterize structures of frozen deposits and reflect their formation conditions. There are several classifications of cryotextures based on various principles (French and Shur 2010).

Despite their complexity and variety, cryotextures are an important diagnostic sign of deposit freezing conditions. Syngenetically frozen deposits are mostly characterized by lenticular, stratified, and stratified-reticulate cryotextures. Reticulate cryotexture is characteristic for epigenetic permafrost; in taberal deposits, most common is the cellular cryotexture. Massive cryotextures often emerge in deposits thawed in situ, but it can also occur in deposits formed in extremely dry frosty conditions. Understanding these differences is important for evaluating geological conditions of archaeological material deposition.

Frost cracking is an important cryogenic process (Yershov 1998: Table 14.1). It is associated with the mechanism of forming polygonal vein structures (Fig. 2a), which are a significant characteristic of permafrost. Frost cracking is a process of temperature-caused deformation of frozen sediments: cracks appear on the surface and penetrate quite deeply into the deposit (3–4 m and deeper, depending on the frozen sediments temperature: the lower the temperature, the deeper the fissure). As the crack fills with ice, snowmelt water, sand, and silt, ice wedges form; repeated cracking results in the wedge-like stratified ice bodies with a varying mineral component (sand, loam, and silt aleurites), organized in a polygonal system.

Multiple iterations of this process lead to formation of cryogenic structures and specific topographic forms (Fig. 2a). In deposits of homogeneous composition and mechanic properties, rectangular crack networks are formed; in heterogeneous deposits, more sophisticated polygonal patterns with five or more sides form. The network of cracks is oriented parallel to any open vertical surface (e.g., scarp, cliff, or another crack of any origin or erosional channel).

As a result of frost cracking, polygonal ice wedges form (Fig. 2a, d, e); they are a network of linearly elongated ice-saturated lodes with the insides composed of frozen deposit (ground columns or polygons). Polygonal lode formations are subdivided into four types: ice wedges (wedge-shaped ice bodies with a varying mineral component), originally sediment-filled cracks, primary sand-filled veins, and casts or pseudomorphs (cavity left by thawed ice wedge and back-filled with secondary deposits).

Ice wedges can form in previously deposited sediments as a result of postdepositional freezing due to increasing climate harshness, and thus epigenetic ice wedges form. Alternatively, they may grow simultaneously with deposit accumulation as a result of sediment freezing resulting in syngenetic ice wedges (Fig. 2d). The syngenetic ice wedges have greater vertical formation thickness than the epigenetic ones and can form multilayered structures measuring tens of meters vertically.

Epigenetic ice veins are short (generally, their height does not exceed the depth of annual temperature fluctuations) and symmetrically triangular in section, with a clear wedge end (Fig. 2c), while syngenetic veins in section rather resemble

Permafrost Digging, Fig. 2 Permafrost deposits and cryogenic structures. Permafrost Digging, Fig. 3 (continued)

a column with a gradually thinning bottom turning into the residual part of the elementary ice vein (Fig. 2b).

Originally sediment-filled cracks and primary sand-filled veins basically serve as an indicator of severe climatic conditions (cold and arid/hyperarid) in which frozen sediments formed. They do not strongly affect the position of archaeological materials enclosed in the deposits.

The entire set of abovementioned cryogenic characteristics is most expressive in the area of low-temperature, mostly subaerial syncryogenic deposits, namely, the *Ice Complex deposits* (Soloviev 1959). They are common in northern East Siberia mostly in the vast coastal lowlands but also known in the Central Yakutian lowland (Romanovskiy 1993; Schirrmeister et al. 2013,), in the northeast North America (Kanevskiy et al. 2011), and in the intermountain basins of Northeast Russia (Soloviev 1959).

Ice Complex deposits are represented by ice-rich silt sandy loams, clay loams, and sands penetrated by syngenetic wedge ice (Fig. 2e). These deposits are polygenetic in nature both in terms of cryogenic characteristics and in terms of deposit genesis. These deposits include alluvial, lacustrine, slope, and aeolian sediments that accumulated in Middle and Late Pleistocene in the conditions of extracold, mostly arid, sharply continental climate with low-temperature frozen substrate present. Total ice content in the complex deposits is very high and changes zonally, from 50% to 70% in the Central Yakutian lowland to 80–95% on the northern coast of the Yana-Indigirka lowland and the New Siberian Islands. The thickness of the Ice Complex deposits reaches 60 m or more.

The development of syngenetic permafrost plays as important impact factor on archaeological contexts that form within this depositional environment. It is well studied at the **Yana site** (71° N) excavations in the northern Yana-Indigirka lowland (Pitulko 2007; Pitulko et al. 2013). The cultural layer occurs approximately in the middle of the second alluvial terrace of the Yana River at 7.5 m above the water level. Ice-rich sediments hosting the cultural remains are typical Ice Complex deposits (Pitulko and Pavlova 2016). The terrace body consists of two members of bedded structure (Fig. 3a) which are penetrated by three generations of the ice wedges. The oldest one is of Karginian (MIS 3) age, smaller veins of the second generation date to LGM, and the youngest generation formed in the Holocene.

Processes involved in syngenetic ice-wedge formation have the greatest impact on the properties of the cultural layer especially on hypsometric position of some portions of the cultural layer and its artifacts (Pitulko and Pavlova 2016). As mineral sediments accumulate simultaneously with the increase in the volume of the ice wedge, some archaeological material that belongs to the deposits next to the contact between the ice wedge and the polygon body gradually becomes displaced as it moves up together with the matrix deposit due to the ice-wedge growth. As a result, in the vicinity of the contact, the cultural layer curls sharply upward (Fig. 3a through e).

This often leads to the frost-mechanical destruction of the artifacts but also causes potential problems with radiocarbon dating and the microfossil record research. Because of this upward move of both the material and the matrix sediment at the

Permafrost Digging, Fig. 3 Cryogenic deformations in layered frozen deposits due to the formation of syngenetic ice-wedges: generalized lithostratigraphic sequence of Quaternary deposits for the Northern Point locality of the Yana site complex (**a**); schematic block diagram for cryogenic deformations of the culture-bearing layer caused by development of syngenetic ice vein (**b**); spatial distribution of in situ mapped cultural material of the Northern Point locality, excavation map (**c**); hypsometric profile along (*c-d*) line within 13 to 16 m elevation in absolute marks viewed from South (**d**); spatial distribution chart for archaeological material along (*c-d*) line viewed from North (**e**). (After Pitulko and Pavlova 2016)

margins of the polygon ground body, which can be >1 m wide, the material for ^{14}C dating and the dispersed sediments containing pollen grains and other microfossils are moved to levels where they are asynchronous to sedimentation.

Notably, they formally preserve characteristics of in situ condition, being located in permafrost deposits at a significant distance from the ice-wedge margin and depth from the surface as the culture-bearing horizon at Yana site occurs at about 7.5 m depth. If ^{14}C dated, such materials return ages of 28,000 ^{14}C years BP and provoke erroneous conclusions on the age of the deposits, which in fact are twice as young. Then it should be realized that the same regularities in vertical matter redistribution work within polygonal ice-wedge structures everywhere, affecting individually deposited objects as well, if they are close to the polygon boundary.

The same cryogenic bulge which moves the materials away from its original position inside the frozen deposits participates in formation of material concentrations when frozen deposits thaw. As a result, secondary concentrations of the material may appear both below and above the original cultural layer (Fig. 4) having the same age as the source horizon. Such concentrations have some formal signs of a cultural layer but are formed entirely by cryogenic processes. Understanding such patterns can help correctly evaluate dating results from permafrost deposit sections and cultural remains distribution in archaeological sites (Pitulko and Pavlova 2016).

The growth of syngenetic ice veins can lead to disconnection of single horizon of culture-bearing deposits by several meters and formation of distinct cultural layer fragments, enclosed within a ground body of the permafrost polygon. In this case, the cultural layer present within an individual polygon usually continues in adjacent polygons (Fig. 3c–e). Thus, an anthropogenic structure (e.g., a residential area) can be divided into several fragments by the ice vein growth.

In the process of epigenetic vein growth, culture-bearing deposits are moved laterally within narrow areas (up to 0.5 m wide) when the vein penetrates below the cultural layer level. Vertical movement of the material along the contact with the vein generally remains insignificant.

Pseudomorphs, or ice-wedge casts, form when frozen deposits thaw, resulting in through-like depressions. They are filled with various loose deposits containing, among other things, faunal remains and artifacts, which were previously held by the permanently frozen culture-bearing deposits. Under certain circumstances, such concentrations can be mistakenly accepted as in situ materials, leading to misconceptions (Velichko et al. 1997).

Although not many of archaeological sites are known within the Ice Complex extent (Pitulko et al. 2016a; Pitulko et al. 2017), the potential of this area, considering how little of it has been studied, is immense. Due to the permafrost conditions, informational value of each site is extremely high.

Basic Destructive Processes Transforming Frozen Deposits

Since cryogenesis of the lithosphere is a complex interplay of various processes associated with phase transformations of moisture in rocks, their cooling (sediment freezing, permafrost aggradation) and warming (thawing, permafrost degradation), it naturally involves a number of destructive processes that transform frozen deposits. The Ice Complex deposits discussed above are especially sensitive to changes in heat energy influx and to the impact of a combination of erosion processes due to the highest ice content.

The principal destructive factor affecting perennially frozen deposits is thermokarst, which, as a consequence of thermal conversion of ice-rich permafrost, results in the formation of negative relief forms: depressions, lake basins, and *alases*, or flat-bottom lake basins of drained lakes, where peat bogs develop. Permafrost degradation causes significant surface subsidence due to the loss of the frozen deposit volume from thawing and packing of thawed original deposits, as they become taberal (thermokarst) deposits.

Formation of thermokarst lake basins is associated with thawing out of the upper part of ice veins, under the influence of atmospheric heat and local hydrology. On the geologic time scale, thermokarst development positively correlates with warming events and raising annual

Permafrost Digging, Fig. 4 Yana site complex, Yana B area, testing trench on the river bank slope at Dvoinoy polygon unit (**a**) and lithology sequence observed in NE excavation wall at grid line Q6F052 - Q6F049 (**b**). P

precipitation. Water is the most important agent of this process due to its potential for erosional activity, heat accumulation, and transport.

Extensive permafrost degradation and thermokarst development are accompanied by widespread thermodenudation, which combines the cryogenic destruction of sediments on the surface and the transportation of its products to lower elevations. Thermodenudation of frozen deposits is accompanied by a whole variety of slope processes (water gravitational and gravitational). The most noticeable contribution in thaw transformation of frozen deposits is made by landslide (defluction, cryogenic creep) and solifluction processes (Fig. 4). The specific process occurring depends on the water saturation degree, the speed of deposit movement, and the steepness of the surface where it takes place.

Solifluctional and other slope processes can participate in the formation of the primary archaeological context at the base of a slope as well as in the secondary transformations of the cultural horizon formed in situ. A characteristic example of the former comes from geoarchaeological studies of the Paleoeskimo at the Tayara Site on Qikirtaq Island in the Canadian Arctic. As the site is formed, cultural remains got buried in the deposits resulting from cover solifluction reworking glacial-marine deposits. This process buried the northern part of the site. The speed of solifluctional deposit flow is estimated around 1.68 to 2.86 cm/yr for approximately 350 years. As a result, three successive cultural horizons were formed (Todisco et al. 2009). Remarkably, postdepositional process did not change features of spatial distribution of the material associated with human activities, as confirmed by statistical analysis of stone artifact concentrations. At the same time, researchers found that the orientation of bone remains partially changed due to the impact of low-energy surface runoff (Todisco et al. 2009).

The impact of slope processes on culture-bearing deposits can be significantly higher, as evident at such Paleolithic sites of the Russian Plain as Kostenki (Holliday et al. 2007), Khotylevo (Gavrilov 2015), and Zaraysk (Amirkhanov et al. 2009), where changes in culture-bearing deposits were most likely caused by cryogenic creep. Today there is no permafrost at or around these sites, but it existed here during the LGM. Despite slower flow speeds (measured in mm/yr), the long-term character of this phenomenon is apparent in significant changes of culture-bearing horizons, specifically in vertical distribution of material. Consequently, false sequences can appear, as the deposit moves without losing structural integrity. If locally developed cracks open slowly and gradually fill with materials from the culture-bearing horizon, material concentrations not associated with human activities, similar to those found in the Zaraysk site excavations (Amirkhanov et al. 2009), can form.

An important result of frozen deposit transformation when thawing is the formation of pseudomorphs within ice wedges (Figs. 5 and 6). These are secondary polygonal structures resulting from ice veins thawing out and gradually filling with sediments. It is easy to imagine that archaeological material present higher in the profile (or to the side of the thawing vein) will inevitably be enclosed in the body of such formation. They are widely represented, for example, in Quaternary deposits in Central and East Europe, where permafrost is not currently present, and within the current cryolithic zone. Along with other signs of the paleo cryogenesis, ice-wedge pseudomorphs were noted in the profiles of some Paleolithic sites (Khotylevo, Yudinovo, Zaraysk, Kostenki, Eliseevichi, and many others).

Under certain conditions, the cultural material of the site can be completely moved into depressions formed by thawing of the ice wedges, with no material left in the original position and then with no signs for presence of near-horizontal culture-bearing layer. The Zhokhov site (Pitulko 2013) is one of the best examples of such circumstances.

The **Zhokhov site** (76° N, Zhokhov Island, New Siberian Islands) is one of the northernmost archaeological sites in the world and the oldest reliably documented evidence for human habitation in the High Arctic about 9000 years ago. The total excavated area at the Zhokhov site is 571 m^2, which is estimated to constitute approximately 10% of the total area of culture-bearing deposits.

Permafrost Digging, Fig. 5 Excavations in permafrost, Zhokhov site, New Siberian Islands. Permafrost Digging, Fig. 6 Accumulation model for frozen culture-bearing deposits of the Zhokhov site, New Siberian Islands, from the artifact and bone rain evolved due to human habitation, to ice-wedge casts filled with cultural material together with matrix sediments

It yielded a large collection of organic and lithic artifacts, faunal remains, and the oldest human remains in the Arctic (Pitulko 2013; Pitulko et al. 2015).

The site is located on the accumulative denudation plain, developed on the Ice Complex deposits (*yedoma)* represented by syngenetically frozen, horizontally wavy layered clay-sandy and

sand-clayey aleurites with a small admixture of gravel and gruss, containing occasional thin plant roots. Thick syngenetic ice wedges developed in these deposits, which formed at the end of Late Pleistocene.

Originally, cultural material from several habitation events was deposited on some near-horizontal, slightly elevated and dry portion of the yedoma plain surface. This plain was subject, at least twice, to the impacts of thermokarst processes caused by warmings in Early (around 96000 years ago) and Middle Holocene (ca. 7000–6500 years ago). A comprehensive study of the Zhokhov site's geological structure has shown that its culture-bearing deposits have a complex cryolithologic structure characterized by varied sediments and genetically heterogeneous underground ice types (Pitulko and Pavlova 2015).

Numerous artifacts and a large amount of faunal remains occur in lithologically varied layers virtually throughout the whole depth (up to 2 m) of excavated deposits; some are scattered, but more often they form large concentrations of cultural material (Fig. 5). The cultural remains deposition indicates a brief rewashing by surface and ground waters, in addition to the slope sediments coming from the outside. At the same time, despite obvious traces of the water flow affecting the artifact-bearing deposits formation, there are no signs of long-distance transport of cultural material.

The site's geological structures, granulometric sediment composition, and radiocarbon dates show that the currently observed artifact-bearing deposits started to form ~7380 ^{14}C years BP as a result of active thermokarst, thermoerosion, and slope (primarily solifluction) processes supplemented by abundant surface water. Their impact caused the top of the Pleistocene Ice Complex deposits to thaw in some areas (probably the ones most utilized by people beforehand), and thus ice wedges started thawing from the top. As a result, spacious cavities, pockets, thermal wells, and channels were developed in ice-wedge bodies and consequently filled with large amounts of cultural layer material mixed with coarse debris from the above slope and proluvial deposits (Figs. 5 and 6).

Spatial distribution analysis of ^{14}C dates, obtained from various materials (wood, peat, plant remains, bones, and charcoal) within the excavated part of the Zhokhov site, has showed that the excavated deposits contain date series with inversions (Fig. 5b, c) and that more often, younger dates lie below the older ones (Pitulko and Pavlova 2015). This is important evidence of the cultural layer gradually sliding into surface depressions: younger deposits shifted down into the lower part, while the older ones would follow them with the next portion of material to settle above the younger ones. Cultural material was buried by slope deposits in several stages with diminishing intensity and refroze soon after redeposition.

As a result, the archaeological material preserved in secondarily concentrations as artifact-bearing masses filled thermokarst and thermoerosional depressions of the landscape. Nevertheless, cultural remains maintain general elements of the original spatial structure of the site and were not influenced by long-distance material redeposition, as confirmed by the spatial distribution pattern of the most numerous categories of finds (in the tens of thousands; Pitulko et al. 2015). Instead, it is demonstrated that the distance covered by the artifacts due to gravity and/or water transport probably does not exceed 10 m relative to their original position. In fact, original cultural layer of the site, along with sediment particles coming from the polygon body deposits, was transformed into ice-wedge pseudomorph filling (Fig. 6). The thawed top of the vein has been stripped in the lower part of the section. The plane position of material concentrations within the Zhokhov site excavation repeats the polygonal ice-wedge pattern (Pitulko et al. 2015).

Most likely, the Zhokhov site case is a single known example of complete demolition of the original archaeological context followed by its reburial in the ice-wedge casts and refreezing. At the same time, ice-wedge casts as evidence of paleocryogenesis and geological features are well-presented in the profiles of Quaternary deposits which contain archaeological materials.

Pseudomorph formation can cause faunal remains and artifacts to group into concentrations

that can be mistakenly assigned to past human activity. For example, the spatial arrangement of mammoth remain concentrations and profile elements at the Timonovskaya and Eliseevichi sites had been described as human-made "dugouts" or semisubterranean Upper Paleolithic dwelling structures (Krainov 1956). These so-called dwelling structures are actually large ice-wedge casts (Velichko et al. 1997). In their fill, there was archaeological material from the overlying

Permafrost Digging, Fig. 7 (continued)

culture-bearing in situ horizon. These features reflect postglacial permafrost degradation in the Russian Plain paleopermafrost zone (Vandenberghe et al. 2014).

Within the modern permafrost zone, especially on the Arctic sea shorelines and islands, and in river valleys, thermoabrasion and thermoerosion contribute greatly to the Ice Complex destruction (Are 1980; Gavrilov et al. 2006; Overduin et al. 2014). Thermoabrasion causes destruction, including sudden and quick, of a large number of archaeological sites – mostly sites of the arctic sea mammal hunters, located directly on the coastline (Hollesen et al. 2018). Wave action results in intensive retreat of sea cliffs built from frozen deposits. The coastal erosion rate averages 10–12 m/yr. but can be significantly higher, reaching 50–60 m/yr. under certain conditions. Thermoerosion of riverbanks in their concave portions also frequently develops dramatically, at high rates (Fig. 7). According to long-term observations around the Yana site, the average rate of bank retreat is ~6 m/yr.; however, during some seasons it reaches 20–30 m (Pitulko and Pavlova 2016).

High retreat rates for riverbanks built from frozen deposits are observed everywhere in Siberia, as well as in Alaska, where the retreat of a frozen cliff on the Itkillik River was studied. Over the observation period (2007–2011), on one of the sections of this cliff, the average speed of retreat was 45.4 m/yr., with the maximum of 81.1 m/yr. recorded on one of the bank segments (Kanevskiy et al. 2016).

The mechanism of these processes includes the repeated formation of a deep erosion niche, deeply cut into frozen deposits of the bank basement, and the fall of frozen deposit blocks after the tensile strength limit is reached (Fig. 7). The resulting vertical frozen walls actively retreat under the impact of termodenudation processes and the slumping of the upper cliff deposits. Thus, over a short time, entire bank segments are massively destroyed, and the river further reworks frozen deposit blocks.

For archaeological research, such destructive processes are important because they can result in natural destruction of archaeological sites before they are studied or even found. Besides, such falls can move artifacts and bone remains to the present river deposits, or archaeological material can get enclosed in deposits that do not correlate with them by age. Meanwhile, not only individual artifacts that have completely lost spatial relations but also whole blocks of the cultural layer can be buried in the modern river deposits. These blocks could be undisturbed (partly or completely thawed), with fully preserved attributes of the intact layer or even the structure as well as spatial relationships of artifacts (Fig. 8). Ignoring such possibilities inevitably results in erroneous interpretations of the material.

Frozen deposits were completely lost or significantly transformed in a large portion of the former permafrost distribution. For instance, in the north of East Siberia, active development of lake thermokarst during the postglacial, about 13,000–12,000 years BP (Kaplina 2009), leads to the relief transformation of vast areas of coastal lowlands with the formation of numerous lakes and the alas deposit complex. By 11,000–10,000 yrs. BP, lacustrine sedimentation had been replaced by palustrine, and the *alas* topography formed. Throughout the Holocene,

Permafrost Digging, Fig. 7 Thermoerosional destruction on the left river bank of the Yana River in the Northern Point area of the Yana site complex: (**a**), instrumental recorded dynamics of the bank erosion in the western part of the excavation area: 1, topography of the area with 2 m height step contour lines; 2 to 6, terrace edge position recorded in different years of observation (2, September of 2007; 3, September 2013; 4, September 2014; 5, June of 2016; 6, September 2016); 7, the lowest water stand in 2016; 8, the highest water stand in 2016; 9, ground polygons that contain cultural layer; 10, modern alluvium covering thawed (thermoeroded) polygons; 11, modern alluvium covering polygons in which cultural layer was excavated in 2003–2015; 12, collapsed frozen blocks with cultural layer which was excavated in 2016 after collapsed blocks were discovered after the water drop; 13, ice wedges in bank exposures; 14, thawed ice-wedge body covered by modern alluvium; 15, channel alluvium. Mechanism of thermoerosion process: formation of deep niche cut by water in frozen deposits at the Northern Point excavation area (**b**) and catastrophic collapse of large frozen blocks that led to loss of the part of the area prepared for excavation (**c**). (Photo credit: Elena Pavlova)

activation of thermokarst processes was observed ~9000, ~4000, and ~2000 yrs. BP, with the most intensive peak at 9000 yrs. BP. This process is often considered a special variant of peneplanation, called thermoplanation (Baranova and Biske 1964).

As the upper part of perennially frozen masses undergoes thermal transformation, they can be completely lost in significant expanses and to a significant depths. For instance, the depth of large thermokarst basins (*alases*) can reach 20 m and more (in case of inherited development of the lake and significant thickness of deposits). Their area can reach tens of square kilometers. Mass permafrost degradation has resulted in the loss of a significant part of the Ice Complex deposits.

Evidence of such degradation was found at **Urez-22** location (MKR/UR22) in the northern Yana-Indighirka lowland (Fig. 9). This part of the lowland has experienced mass thermokarst transformation in the Holocene. The site is situated in the upper reaches of the Bulchug-Yuryuete Creek, a small left tributary to the Maksunuokha River. Its coordinates are 71°42'44.5" N and 141°12'48.4" E. In the area of interest, the creek runs from southwest to northeast. This site provided an experience of investigating an archaeological object that originally contained mammoth bone remains and a microblade lithic industry but then had completely lost its original structure and spatial integrity (Pitulko et al. 2016a).

The postdepositional history and chronology of the archaeological material from Urez-22 (MKR/U22) were reconstructed based on field observations, evaluation of the relationships among the modern landscape elements, geology of the site, and the assessment of relationships

Permafrost Digging, Fig. 9 Site Urez-22 (MKR/UR22). (**a**), the view from the west from the side of the helicopter; (**b**), exposures on the left bank of the Bulchug-Yuryuete Creek; (**c**), lithostratigraphy chart for the location. Legend: 1, Ice Complex deposits (syngenetically frozen sandy silt and clayey silt with plant roots on growing position); 2, taberal deposits (thawed and refrozen Ice Complex deposits, fine-grained silt with organic stains); 3, lake bog deposits (ice-saturated fine-grained silt with organics and interbeds of plant remains, peat lenses, brush twigs and roots); 4, solifluction sediments (clayey and sandy silt with organic stains and peat lenses); 5, unexposed portion of the cut; 6, peat lenses; 7, shrub branches and roots; 8, faunal remains; 9, first-generation ice wedge; 10, second-generation ice wedge; 11, horizon with tiny ice veins; 12, paleolake ice; 13, reconstructed position of paleo thaw lake bottom; 14, facies number; 15, radiocarbon date. (After Pitulko et al. 2016a)

among the site's structural elements supported by dating results. There are four members of Quaternary deposits, each corresponding to a certain stage of natural development of the area.

The oldest syngenetic permafrost deposits of Member I formed in rather severe but stable conditions of the watershed surface in the second half of Late Pleistocene, as indicated by the development of

thick first-generation ice wedges. The second-generation ice wedges formed during the Sartan glaciation (MIS 2). Based on the available dates from mammoth bone remains, human activity episode here presumably took place 12,500 yrs. ago.

The development of thermokarst processes at the Pleistocene-Early Holocene boundary lead to the active destruction of thick permafrost deposits (Member I), thawing of the Ice Complex deposits and formation of the thermokarst deposits (Member II), and formation of a thaw lake reservoir. Bone remains of mammoths and lithic artifacts were reburied in the basin of this reservoir (Member III). Quite recently, it was followed by the formation of erosional channels providing drainage for this area and stabilizing the development of thermokarst processes. The reburied archaeological material, which had been brought into the seasonally thawed layer by solifluction processes, gradually moved down the slope, forming secondary concentrations in crossings of the ice wedges forming permafrost polygons. Repeated many times, this process resulted in material concentration at the base of the slope, in Member IV deposits.

Based on this reconstruction, the original position of the artifact-bearing horizon cannot be established, as it ceased to exist 11,700 radiocarbon years ago, in the final Pleistocene, at the early stage of permafrost transformation by thermal processes. In the Holocene, the deposits enclosing the redeposited archaeological material formed.

Based on the fieldwork experience, we can note that many sites of that time and slightly older, dating to the postglacial time, probably suffered a similar destructive thermokarst impact. This is supported, in particular, by the data from the Achchagyi-Allaikha bone bed in the lower reaches of the Indighirka River, where the primary concentration of mammoth bone remains and occasional artifacts was redeposited by a similar scenario (Nikolskiy et al. 2010).

In the archaeological record of arctic East Siberia, sites dating to the Pleistocene-Holocene boundary are most common. Cultural deposits of all known sites had been significantly transformed due to permafrost degradation of the area, marked by the *alas* complex development 13,000–8000 years BP. Many sites of that age may have been lost due to mass thermokarst processes and landscape reconstruction during the Pleistocene-Holocene boundary. Thus, there are reasons to consider the observed breaks in the archaeological record and/or the small number of known sites, dating to various intervals, a taphonomic gap determined by degradation of permafrost deposits.

Finally, it is notable that, in the area studied, there are no archaeological objects from the middle or the second half of Holocene. In many permafrost regions in Eurasia (Northeast European Russia, Taymyr, and Chukotka), the number of archaeological objects of the second half of Holocene greatly exceeds that of earlier ages. The degrading permafrost of the arctic Northeast Siberia and the development of thermokarst with formation of lakes and alases could have limited the presence and activity of human populations in the area, causing people to completely or partially leave in the middle of the Holocene.

Thus, within the present permafrost zone and in the area of its former spread, thermokarst is the leading relief-forming factor among the destructive processes of frozen sediment transformation. As a taphonomic factor, it impairs the adequacy of the archaeological record. Destructive thermal and cryologic processes impact the integrity of primary (in situ) archaeological contexts, drive the formation of secondary (redeposited) archaeological contexts, and effect the integrity of archaeological materials through the risks of mechanic (frost weathering), chemical (chemical weathering), and biological degradation.

Excavating Permafrost Archaeological Contexts

The Yana-Indighirka and the Kolyma coastal lowlands in East Siberia are lake-alluvial plains built from the surface by syngenetically frozen aleurites, including numerous structures of polygonal vein ice, that is, Ice Complex deposits. These deposits contain the cultural layers of archaeological sites in the area. A total of 17 archaeological sites are currently known, most of which (n = 15) date to MIS 3 and 2 (Pitulko et al. 2017), while only two of them date to the first half of the Holocene.

Experience of archaeological excavations in this specific environment was received first in Zhokhov Island during the investigations of Zhokhov site in 1989 and 1990 (Pitulko 2013) and then at the Yana site since 2001 (Pitulko 2007). It was further developed in a number of survey and excavation projects in the northern Yana-Indighirka lowland performed within the past 20 years. Although excavation technology and strategy has to be adopted to every particular site, based on the local geological structure and topography, there are basic principles, which are presented below on the Yana site example.

The Yana site locates on the left riverbank in the low reaches of the Yana River, about 100 km inland from the Arctic coast. Its coordinates are 70° 43' N and 135° 25' E. The site has a complex spatial structure (Pitulko et al. 2013). The Northern Point locality is the most studied part of the site, where total investigated area of the cultural layer exceeds 3500 m^2. It occurs about 7.5 m above the water level in the middle of the river terrace which is formed by ice-rich deposits penetrated by three generations of ice wedges.

These features make excavations at the Yana site quite labor-consuming, but the excavation technique can be summarized as a simple set of procedures (Pitulko 2007). Since the whole mass of the terrace is frozen and STL thickness does not exceed 0.7–0.8 m, excavations cannot be fast.

Areas suitable for cultural layer excavation are prepared by removing overlying deposits in a stairway fashion. The area is limited by the polygon body size, while the number of areas being prepared is determined by the number of investigators. It is advantageous to perform simultaneous removal of overlaying deposits and excavations within several polygons, as well as the initial stripping.

Excavations of the cultural layer are performed within strips of the polygon body, up to 1–1.5 m wide and 2 to 6–8 m long. These strips successively uncover the cultural layer, as the "frontal" excavation moves toward the inside of the polygon body. Exceptionally rarely, it is possible to obtain a larger section. Before uncovering each strip, the overburden above is removed as described.

Most generally, the methodology of excavating the Yana site is as follows:

1. Step-wise removal of overburden to organize the work area (Fig. 10a).
2. Mounting special scaffolding along the front of the prepared area of the layer for occupational safety (Fig. 10b).
3. Hand troweling the cultural layer within the 1 × 1 m grid to the depth of daily thaw, stopping at the frozen level; matrix sediment is collected into buckets within each 1 × 1 m excavation unit (Fig. 10c, d).
4. Screening the removed sediment to collect the missed smaller cultural material by using a 2 mm zinc-coated screen and any low-pressure gasoline pump (Fig. 10e).
5. Photographing and recording the in situ layer material with any suitable total station, numbering, and bagging the finds (Fig. 10f).
6. Removal of the backdirt pile, along with products from brows and side surfaces collapse of exposed ground parts of permafrost polygons that are delivered naturally over the ice veins.

Backdirt and these visco-liquid deposits are removed by runoff channels, built along ice veins, with the help of water delivered by a portable fire pump capable of producing pressure of 5–6 ATM. Runoff channels have to be maintained primarily for removing the large amounts of water entering the excavation due to the natural thawing of deposits located in the upper part of the slope; the runoff measures in thousands of cubic meters daily.

Drainage is universally important in all permafrost excavations. Considering this, excavation areas should be arranged down the slope in order to provide natural runoff or to prepare collection areas, from which the incoming water can be pumped. Water collectors should be located in areas with no cultural layer or where it has been excavated; a good option is creating a caisson inside thick ice veins or in pseudomorphs, provided there is no cultural material in them.

If the frozen front has retreated far inside the bank, several rows of polygons have been

Permafrost Digging, Fig. 10 Excavation technology based on the experience of archaeological work in the permafrost environment, on the example of the Yana site project 2001–2018: removing of the overlaying deposits by the method of lateral steplike digging (**a**), preparation of one-meter-wide strip of the cultural layer for excavations along the ground polygon body side (**b**), excavation of the cultural layer by 1 × 1 m units, the matrix sediment has to be collected by buckets and then transported for screening station to be screened for small artifact fraction (**c** and **d**), recording the artifacts with total station (**e**), water screening of the matrix sediment on 2 mm mash with low-pressure water pump (**f**). (Photo credit: Elena Pavlova)

prepared and stabilized, drainage has been arranged, and the area being investigated is optimal in configuration and size, it is better not to wash away the backdirt. Instead, the backdirt material helps stabilize thawing, which can be excessive. In other words, in any situation when the deposit washing can be avoided, one should not use water to dispose of the removed overburden.

Scaffolding is a crucial component of fieldwork, which prevents sliding of the investigated areas, establishes crash barriers against mudflows, and, as roads and bridges, arranges a washing area for water screening and working with the cultural material. To

construct these, a 1.5–1.7 kWt rotary hammer and a generator of at least 2 kWt power are needed as well as chainsaw, axes, and hammers. The same tools are used to create stabilizing constructions to prevent sliding when excavations stop. These operations are labor-consuming but inevitable.

Despite some unique aspects, the excavation described above differs little from the routine procedures well known to any field archaeologist. However, the strategy of such works is different in its core: researchers are basically organizing controlled erosion in the area of interest and manipulating it to their benefit. We should stress that such investigations cannot be planned for one season; a 3- to 5-year cycle is required.

Handling the Excavated Materials

Accelerated thawing methods can be considered when extracting materials from the layer but generally should be avoided for various reasons. In cases when their use is inevitable (e.g., to expedite the extraction of an item which could be lost or damaged otherwise), the most harmless method is watering *the matrix sediment* from a household water sprayer and removing thawing sediment particles with a fine-tip tool.

Soaking the item itself should be prevented with the help of some isolating cover, because excessive moisture leads to the item salinization, which can damage it while drying. Using hot water is strictly forbidden: the temperature of the water used in such cases has to be as close to that of the layer as possible. Alternatively, one could use a heat gun or a similar machine. In this case, however, the item being extracted should be covered with a moist mat to prevent its fast and uneven drying.

In case a bone, tusk, or wooden item is large in linear sizes and therefore cannot be extracted quickly (it is easy to imagine a situation when it is being extracted over a few days or even weeks), it is necessary to isolate its exposed part from the environment to avoid its uneven drying. Bandages of mica-coated paper, which prevent formation and expansion of cracks and facilitate slow drying, should be used.

Archaeological items extracted from excavations in the cryolithic zone have to be dried at temperatures maximally close to those of the deposit. If this operation is performed in the open air, it should be done in the shadows to prevent discoloration. Indoor drying is preferable; this is a slow process, and air circulation is very important here. A household fan can easily do the job, but it has to be placed some distance from the artifacts to prevent fast drying.

Dried organic items can be wrapped in paper or put in perforated ziplock bags for continued evaporation. Long-term storage of packed materials in airtight boxes is undesirable: it will inevitably cause rotting. For this reason, boxes with materials prepared for transportation should only be closed at the last moment. If items are stored in cardboard, ventilation holes should be cut in boxes. Ideal containers for field storage and transport of these artifacts, including faunal collections, are ventilated plastic boxes (e.g., ones used commercially for storing and transporting produce).

Items in poor condition and requiring professional restoration have to be packed, at the very minimum, with bandages of medical gauze or mica-coated paper saturated with ethanol. An item prepared in this way has to be placed in a spacious ventilated bag (double ziplock); its bandage should periodically be resaturated with alcohol. One should not try to glue or saturate the item because this will complicate restoration and can have undesirable consequences for the item itself (Burshneva and Pitulko 2014).

Bone, antler, and mammoth ivory artifacts, prone to deforming when dried, should dry in gypsum containers, made according to the artifact size. For organic items, an antiseptic treatment is recommended to prevent microbial degradation of the material.

Materials extracted from permafrost deposits should be stored at temperatures maximally close to the layer temperature, ideally in a cryostorage arranged for this purpose. At the very minimum, they should be placed in a controlled environment (both temperature and humidity).

Conclusions

We have summarized information on permafrost deposits, their emergence, current spread, and peculiarities. Clearly, these deposits make a rather unique and irregular environment for archaeological excavations. Each permafrost site has features mostly determined by genesis and time when

deposits enclosing and capping cultural remains were formed as well as by thickness of the latter, as it is shown on several practical examples. Besides, excavations are greatly impacted by the exposure of the study area and the current state of the surface, including its inclination, STL thickness, and the presence of erosional landscape features.

Studying Pleistocene archaeological sites with a thick overburden is technically very complicated. Excavations of Holocene-age geoarchaeological objects appear less complicated due to relatively thin overburdens. Unlike with Pleistocene sites, here excavations can be carried out over large areas. To increase efficiency, it is feasible to apply a three-stage organization of the excavation, when one part of the area is cleared to frozen ground for thawing, another is drying, and the third is being actively excavated. The main problem of arranging excavations in the cryolithic zone is water drainage.

Thawing should not be accelerated artificially, since the consequences of that are hard to predict and overcome. Any attempt to melt permafrost will lead to the formation of a growing water-filled hollow.

The most important drawback of artificially accelerated thawing is the excessive dampening of the cultural layer, which turns into a slurry when water runoff and evaporation are too slow. With natural thawing, this problem is minimal. Thus, control of the thawing process is a defining feature for excavating cultural layers in permafrost conditions.

All stripping operations in permafrost sites should be done by hand, as thawing allows. To remove backdirt, various construction instruments, including pumps, can be used. Sediment stripping and, of course, cultural layer excavations by water washing are unacceptably destructive.

Elsewhere in permafrost regions, erosion fights against permafrost. For this reason, to preserve information from archaeological objects within its boundaries, archaeologists should be systematically surveying and excavating sites. It is important to work ahead of perspective commercial exploration, since excavating in permafrost conditions is a prolonged and labor-consuming process.

Practical recommendations for working in permafrost conditions consist of using straightforward procedures, machines, and instruments, mentioned and discussed in detail above. Success of excavations in the permafrost deposits completely depends on the degree of preparation, technical equipment, and the researchers' knowledge of permafrost characteristics and specific features of permafrost deposits at the site.

Peru: Cultural Heritage Management and Education

Jorge E. Silva Sifuentes
School of Archaeology, San Marcos University, Lima, Perú
Ricardo Palma University, Lima, Perú

Introduction

The Peruvian Cultural Heritage

Peru's cultural heritage includes the legacy, tangible and non-tangible, of its pre-Hispanic cultures, those belonging to Colonial and Republican periods, present-day cultural manifestations, either urban or rural, the culture of native communities in the tropical forest and the highlands, besides the Africans, Asians and Europeans who also brought distinctive cultural customs either in colonial times or later. In fact, all of them have created what Peru is today, and as in the past, we are part of a multicultural country. However, there have been diverse opinions about what cultural heritage is, and on occasions, it has been controlled by the interests of particular dominant groups or social classes that have the political and economic power in Peru.

During the Colonial period, such designation for the Spaniards was related to the idea of valuable antiquities, relics, and monuments. For example, H. Cortés said, "I came looking for treasures, not to cultivate the land as a peasant" (Ravines 1986: 147). Even at that time, governments attempted to protect antiquities of new world conquered nations, as testified by Leyes de Indias y la Política Indiana (Indian laws and Indian Politics) published by Solorzano and Pereyra (Ravines 1986: 148).

Additionally, the division into the "Republic of Spaniards" and the "Republic of Indians" during the Colonial period, in which the former was related to a civilized way of life and the latter to a primitive one, helped to develop an incorrect idea about the past based on values such as grandeur and appearance that encouraged the prejudices of people with different cultural patterns. Even though such division disappeared after the Peruvian independence, social exclusion continued, and the dominant social class that inherited the ideology of the first group built its own parameters about the past based on the criteria of monumentality and aesthetics.

Such discourse admired past and present cultural manifestations as isolated events not necessarily associated with the history and the creativity of people from whom Peruvians descend. Therefore, very little effort was devoted to learning and valuing past and present cultural manifestations.

Definition

Types of Peruvian Cultural Heritage

The Peruvian cultural heritage has been divided based on physical features (monumentality of buildings), fragility (documentary data, pieces of textiles, and organic materials), and time period (pre-Hispanic, Colonial, and Republican epochs); on the other hand, according to its bylaw of Organization and Functions (Supreme Decree 001-2011-MC, May 13, 2011), the Ministry of Culture (Law 29565, 1910) not only recognizes present-day Peruvian cultural diversity but also has also created several departments in order to manage culture. Heritage is divided into Archaeological Heritage, Contemporaneous Nonmaterial Heritage, Colonial and Republican Historic Heritage, and Cultural Landscape. Therefore, the Peruvian cultural heritage includes the following:

Monumental

This may be defined based on size and aesthetic features and includes monuments of pre-Hispanic times (a domestic settlement or the city of Chan Chan), apart from Colonial and Republican buildings (the Church of San Francisco and the

Oquendo or the Osambela Residence). According to Article 21 of Peru's Political Constitution enacted in 1993, in order to become a cultural heritage, it must be declared as such through a Ministerial Resolution.

Documentary Data

This is an endangered type of heritage given its fragility and includes all kinds of texts and documents written in Panama even before the Tawantinsuyu Empire was conquered in 1532 (Varon 1986). Among other texts is one which describes how much gold and silver Inca Atahualpa gave for his freedom and how gold and silver were distributed among the conquerors. Means of conservation for this documentary evidence are mainly devoted to preserving only those documents considered as valuable; however, due to lack of funds and other factors, case preservation within Peru is very difficult. For example, the Independence Act of 1821 was sent to the Vaticano archive for treatment.

Arts and Crafts: Folklore

This cultural expression persists within the context of the modernity and globalization. A large portion of this heritage originates from craftsmanship composed of objects made out of clay, wood, metal, timber, textiles, etc., and vernacular music. According to Oliva (1986), this cultural expression was influenced by the indigenous movement that began in the 1920s, and its demand by tourists and Lima's middle class in the 1960s and 1970s increased its production. As a result, quality of handmade crafts was poor, and in several cases, the tendency was to impose other nontraditional decorative motifs. Craftsmen's reaction was to return to their home to produce with freedom and complete autonomy.

Oral Tradition

According to Millones (1986), it includes life stories, ritualism, songs, legends, and fairy tales and is extremely relevant for Peruvians since the written words did not exist before the Spanish conquest. This heritage is transmitted orally, from generation to generation; makes part of the collective memory of the community; and represents belief systems, values, and the spirituality of a nation; therefore, oral communication is more important than written communication.

Key Issues/Current Debates/Future Directions/Examples

The Role of Education in Peru: Points of View and Controversy

Peruvian educational goals have been a topic of debate since the nineteenth century. Such debate focused on how education should help to integrate and develop the country, and while a group supported its elite character, another group proposed that education should attempt to liberate and redeem the natives. This latter group declared that education had to do with the "Indian Problem," which became a part of a larger dilemma since it would have first been necessary to change the political and economic structure of Peru in order to improve the education (Ames 2005: 358).

At present, studies about the role of education in Peru show that it is just one way of improving social position, obtaining social mobility, and improving living conditions. In other words, education seems to be within a developmental project designed to promote change and modernity. This assumption is supported by data collected by E. Vasquez in the 1950s at Vicos, a community in the northern highlands. Similar results from communities of Lampián, Huayopampa, and Pacaraos, in the Peruvian central coast Chancay River Valley, were recovered by F. Fuenzalida and Carlos Iván Degregori in the 1960s and 1970s (Ames 2005: 360–362).

However, there are different perspectives on this issue. Montoya states that education contributes to losing "cultural identity" because its goal is progress. Formal education does not consider native values and emphasizes western society models. For example, Montoya (2011) remarked that the Summer Institute of Linguistics in the jungle of Peru provided topics with religious orientation. Therefore, Montoya names it "education's contemporaneous myth" (Ames 2005: 365). From the native's point of view, education scares native children since attending class means

ending the relationship between man and nature. According to Ames, Peruvian modern education "leads to the ignoring or destroying of peasant culture and to the acceptance of the dominant ideology" (Ames 2005: 362).

Peruvian cultural diversity has been seen as a disadvantage when it came to the purposes of educational projects, since traditional communities of the highlands and tropical forest seem to be conservative when faced with new cultural patterns. With regard to whether we only need to study cultural diversity or if it is also necessary to apply educational and developmental programs, many questions arise. How should this situation be approached? What is best for these communities? Who decides what is best for everybody?

As previously indicated, scholars differ on these topics. Heise et al. (1994: 14) say, "We disagree with the position of intellectuals who approach the study of traditional cultures with the interest that they remain static, and impose the conservation of their traditions and past. . ." Therefore, the issue of cultural heritage implies a theoretical elaboration, especially if an educational program has to be developed.

Assuming that cultural heritage expresses specific features of a shared social custom of a human group that coexists with other cultural customs, it is necessary to identify and treat all of them equally, since together, they represent the identity of a given society. In other words, the cultural diversity of a country should not be arranged into rating scales because each specific cultural manifestation has its own material representation and way of thinking.

Why shall we consider such a premise? Simply because culture is social, and when an individual permanently socializes, he engages in several interactions, including educational ones. Also, a dialogue involving distinct social actors is opened, and with this interacting process, it is possible to understand the other social actors and to discover that common interests do exist.

Given the fact that in Peru several cultural expressions exist, an intercultural process has been proposed (Zúñiga and Ansión 1997). What is this intercultural process? Scholars concur that it is where populations practicing distinctive cultural patterns share and make their lives. For example, the recent Peruvian and US Treaty for Free Commerce has propitiated intense relationships between particular cultural patterns that influence one another mutually, no matter if one of them plays a dominant role in the relationship. What is important to note here is that both of them have their own cultural patterns and traditions.

However, although interculturality exists in Peru, it requires long-term state support and community participation. In fact, Montoya (2011: 420) believes that its application is still a dream because "cultural conflict" persists, and it is far from being solved since natives are excluded from development and social programs.

Additionally, it has been observed that intercultural processes are sometimes so complex and profound that they are difficult to identify. For example, to what extent did native Mesoamerican and Andean food staples influence North America? Mexican chili, corn, and the Peruvian tomato are just a few. Also, we may ask what highland influences are observed among modern creole populations in the Peruvian coast; for example, the "causa" dish (potato and chili) is well known in Lima, but we do not know when and how it was introduced into the main menu of coastal cities.

Legal System and Education of Cultural Heritage

The political constitution of 1993 not only establishes respect for people's identity but also proposes bilingual and intercultural education based on regional characteristics in order to preserve Peruvian cultural manifestations and meet cultural integration. However, archaeological heritage, Historic period relics and monuments, and archive documents receive a somewhat distinctive treatment since it is first necessary to nominate them as cultural heritage before they are registered in the Peruvian cultural heritage records (Article 21; Article 58, items i, m, r of bylaw of Organization and Functions of the Ministry of Culture).

The General Law of Peruvian Education states that education should be formulated based on

Peruvian diversity, taking into account interculturality and respecting the environment (Articles 7, 8). Consequently, education must affirm national identity without neglecting Peru's cultural, ethnic, and linguistic diversity (Article 9). In order to achieve this commitment, education in native communities should apply special curricula (Article 19), although a common curriculum should be implemented for the entire country (Article 13, item b). Clearly, with this plan, education must be offered in Spanish and in other native languages spoken in the highlands (Quechua, Aymara) or in the Amazon basin.

Actually, intercultural processes need to be implemented in Peru in consideration with its cultural diversity. By 1999, 45 native languages existed in Peru, apart from Quechua and Aymara groups; there were 42 communities and 16 linguistic families in the jungle, 18 of which may soon disappear. Although the 1993 Census registered 3,177,938 Quechua-speaking people, research by anthropologists indicates that 4,500,000 people spoke Quechua by 1999. With the addition of Quechua speakers in the Amazon, the total is 5,700,000 individuals (Montoya 2011: 423, 424, 515).

According to the spirit of both the Political Constitution and the General Law of Education, the Ministry of Culture has approved several guidelines through its bylaw of Organization and Functions. This document recognizes cultural diversity and proposes to support cultural development through intercultural projects. In fact, the goal behind this plan is to affirm Peruvian national identity, sustain its social inclusion, and shape an intercultural citizenship (Sections 3.3.2.1, 3.3.2.2, items f, Article 12, item b).

The bylaw encourages training in the area of cultural management and implementing a network of research and data collecting of present-day cultural manifestations, including traditional native knowledge (Article 12, item h; Article 64, item j; Article 71, item n). With regard to archaeological remains, the office of the Director of Archaeology will propitiate the creation of site museums and centers of interpretation at archaeological settlements so that the visitors understand the significance of past remains (Article 54, item f). Additionally, the office of the Director of Museums will coordinate with university research and data collecting about current cultural manifestations (Article 56, item d).

As stated previously, the Ministry of Culture is supposed to manage all past and present cultural manifestations, besides ethnic and cultural pluralism of Peru, since the state is responsible for policies regarding cultural issues. The Political Constitution of Peru indicates that education should emphasize the progress and development of the country; this goal should be pursued with an open spirit in its citizens which will enable them to participate in this process (Art. 3, Section 3.2, items h, j, also Section 3.3.1, item e).

In addition, recommendations about formation on cultural topics as part of the national educational system will be formulated (Art. 3.3.1, item g), apart from implementing cultural programs through mass-media systems (Art. 3.3.1, item m). In fact, there are already several TV programs portraying different cultural expressions. However, even though it is still early for an appraisal of how educational plans on cultural heritage will be eventually implemented, it appears that the law emphasizes its economic benefits. The expression "cultural industries" (see, e.g., Section 3.2, item h, Section 3.3.1, item f) seems to point towards improving infrastructure (roads, hotels, flying routes, etc.). Interestingly, this law seems to prefer homogeneity rather than diversity, as may be interpreted from its plan of "integrating all the Peruvians" (Section 3.3.1, item m).

On the other hand, promotion of tourism only considers the Ministry of Foreign Commerce and Tourism's participation, but not that of the universities (Section 3.3.1, item p). Why should universities be consultants? The answer is simple; several universities, public and private, have schools of Archaeology, Anthropology, and Tourism. In addition, pre-Hispanic cultural heritage is at least 12,000 years old, in comparison to the Colonial and Republic periods which together are only 519 years old, if we consider the discovery of America as a chronological reference. Needless to say, tourists visit Peru because of its long history and its biodiversity.

Concluding Remarks

The education of Peruvian cultural heritage is the responsibility of both the state and the community. The participation of all social actors may prevent inappropriate decisions that may not be part of long-term cultural plans, such as those archaeological discoveries governments took for granted right after the media pointed out their importance to the country. For example, the royal tombs of Sipan in the mid-1980s, the mummy Juanita found on the Ampato snow-covered peak in the 1990s, and the attention paid to the Amazon native communities at the beginning of this century. However, the positive reactions of people are spontaneous and temporary; they disappear when the political agenda changes.

Establishing educational programs about cultural heritage in Peru implies the consideration of regional particularities since each region contains customs, monuments, and relics that have become icons. Therefore, an intercultural approach is recommended. For example, while the people of Ica, located in the southern coast of Peru, have a historical link with the Nasca culture, the people of the Callejon de Huaylas have a connection with the Recuay culture and the nearby snow-covered mountains of Huascaran and Huandoy. In both of these cases, the creation of specific symbolic meanings refers to concrete relationships established through myths, natural components, buildings, and objects. Peruvian culture, past and present, is the coalescence of those manifestations, and education programs should not neglect them. In other words, the Amazon basin and Machu Picchu form part of this old natural and cultural legacy of the Andean universe.

It is recommended that a bilingual intercultural approach be taken with regard to present-day native communities for educational purposes in order to avoid cultural shock between traditional values and occidental external components which usually represent the dominant culture. By this process, natives increase their knowledge about the exterior world which is unavoidably present in the everyday life of the population. To pretend that people ignore such external knowledge is to deny them their cultural rights to survive and face the world. In other words, people should learn how to live with other cultural components without denying their own cultural patterns.

Petra National Trust and the Challenge of Site Management at Petra

Aysar Akrawi
The Hashemite Kingdom of Jordan, Petra National Trust, Amman, Jordan

Introduction

The site of Petra is one of the most spectacular sites in the Near East, Petra has long attracted travelers and explorers, and archaeological investigations have been conducted in the area since the 1930s. Late in 1985, UNESCO inscribed Petra on the UNESCO World Heritage List on the basis of its "Outstanding Universal Values." On four occasions thereafter, Petra was placed on the "World Monuments Fund's 100 Most Endangered Sites". On July 7, 2007, Petra was selected as one of the "New 7 Wonders of the World".

Petra is located halfway between the Red Sea and the Dead Sea in Jordan (Fig. 1) and has been inhabited for more than 200,000 years. Traditionally the tribes were shepherds and farmers. Today people in the area live in modern hillside towns and villages and Bedouin encampments. The park is surrounded by six main towns, and they are, from north to south, Beidha, Um Seyhun, Wadi Musa, Taybeh, Rajef, and Dlagha (Fig. 2). In recent years, with the arrival of tourists, the inhabitants have moved closer to the archaeological site and earn a living by working on excavations and guiding tourists.

Petra National Trust and the Challenge of Site Management at Petra, Fig. 1 Map of Jordan

Definition

Petra National Trust (PNT) is a Jordanian non-governmental organization (NGO) dedicated to the preservation and protection of the World Heritage Site of Petra. Since its inception in 1989, PNT has worked to bring together people in Jordan and abroad who are committed to that same goal. The Trust is the pioneer NGO in the field of archaeological, natural, and cultural heritage preservation in Jordan. PNT does not set policy but works with the policy makers in the government of Jordan and with other NGOs to achieve its objectives. HRH Prince Raad bin Zeid, as president of the Board of Trustees, oversees the Trust's activities and guides PNT in the implementation of its mission and the fulfillment of its vision.

PNT implements its mission through conducting preservation projects and by raising awareness. PNT was instrumental in 1993 in the creation of the Petra Archeological Park (PAP), a protected area covering 264 m^2. With the aim of decentralizing the management of Petra, in 1995, PNT played a pivotal role in the establishment of a single body, the Petra Regional Planning Council (PRPC), to govern the Petra Region that later came to be known as the Petra Regional Authority (PRA). This authority evolved into the Petra Development Tourism Regional Authority (PDTRA). The role of all these bodies, present and past, is to coordinate the efforts of the many

Petra National Trust and the Challenge of Site Management at Petra, Fig. 2 Map of the PAP, showing the main towns surrounding the PAP

Jordanian governmental departments and other institutions involved within the Petra region to maintain a balance between heritage preservation and tourism development and to promote responsible tourism.

In all its activities, PNT cooperates closely with the Ministry of Tourism & Antiquities (MoTA), the Department of Antiquities (DoA), the PAP, and the PDTRA. PNT is a member of the Advisory Committee of the PDTRA that oversees the management and developments within the PAP and its buffer areas. In its role as an advocate for the preservation of the park, PNT addresses the threats, partly natural and partly human, and alerts the governmental bodies responsible for the management of the site, UNESCO, and other international heritage organizations.

In addition to its advocacy role, and with the support of private Jordanian and international corporations, government institutes, international

diplomatic missions, and private donations, PNT has to date raised funds and implemented 22 projects in the areas of preservation, biodiversity, site management, community and awareness, and tourism.

Key Issues/Current Debates/Future Directions/Examples

Jordan has undertaken a number of measures to resolve the confusion in responsibilities and chain of command of the management of Petra, and in 2009 established PDTRA. PDTRA manages the entire Petra Region of 755 km^2 including the PAP which covers a protected area of 264 km^2. Historically, the PAP was managed by DoA, a subordinate department of MoTA. However, the management of the park now falls under the responsibility of the PAP management body, a subordinate organization that reports to PDTRA. PDTRA reports directly to the Prime Minister and is headed by a Chief Commissioner who is assisted by four deputy Commissioners. The deputy commissioners make up a council called "Commissioners Council" that manage the authority and oversee its affairs.

PDTRA's role is the development of the Petra Region economically, capitalizing on its potentials in tourism. It also plays a role in local community development, infrastructure development, heritage management, and the environment. Jurisdiction over archaeological research, conservation, restoration, and preservation, however, lies with DoA.

Challenges and the Impact of Growth

Site management has been a concern in Petra for at least the last four decades. In the beginning, tourism was minimal and, in general, limited to the most adventurous souls. The inscription of Petra on the UNESCO World Heritage List, however, rendered it incumbent on Jordan to protect and preserve it for the enjoyment, scholarship, and pride of future generations. Yet this sparked the surge in the number of visitors; from 93,000 visitors in 1985, it increased to almost a million in 2010. The sudden increase in numbers of visitors, spurred by the peace agreement with Israel in 1994, abruptly brought to the surface the issue of site management. This situation was compounded by the declaration of Petra as one of the "New 7 Wonders of the World" in 2007. DoA, whose primary concern had been archaeological research, found itself unprepared to effectively manage Petra.

In recognition of the need to protect and preserve this outstanding example of national heritage, as well as the importance of the site for economic advancement, both the government and donor agencies invited international organizations to prepare management plans on five occasions. The first of these plans was prepared as early as 1968 and the latest in 2011. The plans assessed the state of conservation of the park and provided guidelines for the use, development, interpretation, presentation, zoning, protection, and general administration the park.

There is a basic consensus among the plans on the type of management structures and interventions needed for Petra. The approach toward the implementation of the recommendations proposed, however, has been fragmented over the years. Instead of adopting a holistic approach to the recommendations delineated in the plan in their entirety, subprojects were selected for implementation, leading to the imbalance witnessed today. This is due to a number of reasons, which include inadequate participation by related organizations and stakeholders in the planning process resulting in a lack of commitment and follow-up, an insufficient understanding and appreciation of the site values and their potential that leads to an unbalanced approach to development, inexperience in the management of cultural heritage sites, and frequent changes in government management.

The Role of NGOs in Site Management

NGOs have been in existence in Jordan since 1966. The focus then was on natural heritage, and the first NGO established for this purpose was the Royal Society of Conservation (RSCN). It, in contrast to all other NGOs, owns and manages six natural parks successfully. Twenty-three years later, in 1989, the first national NGO, whose focal point was archaeological heritage preservation, was established as PNT. The Friends of Archaeology & Heritage (FOAH) was established in 1990 in Amman, and it focused on awareness

and introducing Jordanian and non Jordanians to the archaeological heritage of the country. It, however, did not work in Petra Archaeological Park, PAP. The NGO "Bait al-Anbat" based in the Liwa of Petra was established in 1997, and its focus is "the development of cultural life in Jordan, to raise awareness of cultural heritage and to develop improved dialogue among civilizations." There are numerous other NGOs working in the field of socioeconomic development, education, special education, handicrafts, and others in Petra. With the exception of PNT, most of these NGOs work independently of the PDTRA and the PAP.

Whereas, there is some recognition by the government for the need to explore innovative approaches to site management and to allow NGOs to participate; it has in effect been inconsistent in its approach. This, to a great extent, is due to the traditional centralized modus operandi of the government bureaucracy coupled with a lack of understanding of the role of NGOs in heritage management. The advocacy role of NGOs is perceived as threatening which exacerbates the situation further. A better understanding of the roles of each of these two stakeholders with the aim of achieving a more complementary partnership in the field of site management is the most effective way forward. NGOs, unlike the government, are in the unique position of being nonprofit and, therefore, not motivated by economic gain; at the same time, they are not overburdened by bureaucracy, which gives them the ability to operate effectively.

Conclusion and the Way Forward

For Petra to be preserved, it must be understood in its totality. A clear-cut strategy for the conservation and management of the site must be developed. The impacts of management decisions on the site's values must be clearly identified and appreciated by the decision makers and stakeholders working together as one team. Only in this way will viable site management plans that are relevant to local conditions be adhered to and implemented with success. Petra is a result of many layers of accumulated historical heritage that needs to be managed and presented in a manner that does not encourage further deterioration. Consolidation of the studies and their recommendations with emphasis on the values that set Petra apart from any other heritage site, using an integrated approach with the participation of those having a stake in Petra, is the shortest and most effective way to achieve this objective.

Introduction

The ancient city of Petra, in southwest Jordan, is among the most widely recognizable archaeological sites in the world. The city was inscribed as a UNESCO World Heritage Site in 1985 and has more recently been popularly elected to a list of the "New Seven Wonders of the World".

Originally constructed by the Nabataeans in the late first millennium BCE and later annexed by the Roman Empire, this ancient trading hub features stunning monumental architecture, much of which is carved directly into the red sandstone cliffs for which the site is widely known. The architecture of Petra features a combination of local and classical forms (McKenzie 1990), many of the latter manifested as elaborately carved facades for cave structures in the cliffs that enclose the city. Such is the case for the numerous tombs found within the boundaries of the city, including the widely recognizable "Treasury" (Al Khazneh), which has been featured in several films including *Indiana Jones and the Last Crusade* (1989). The city center also exhibits large freestanding structures, including a colonnaded street, temples, civic administration buildings, and a varied range of domestic structures. The rich religious life of Petra's inhabitants is evident throughout the site. Numerous rock-cut shrines and thousands of relief steles (*betyls*), cultic niches, altars, and inscriptions can be seen carved in the cliff faces in the maze of mountains and valleys surrounding Petra (Wenning 2001, 2010). Petra is also known for an elaborate water management system that once sustained an estimated urban population of 20,000 or more. This system included numerous channels, dams, pipes, cisterns, and storage tanks, as well as pools and gardens (Bedal 2003; Ortloff 2005). Water management features such as dams and cisterns can be found not only within the city but throughout its hinterland as well.

Petra may now be entered by two primary approaches. The *Siq* entrance to the east is taken by most visitors to the site and is by far the more dramatic of the two approaches. This passage through a long, narrow gorge (1.2 km in length and as narrow as 3 m in some areas) through the surrounding sandstone cliffs ends at the iconic Al Khazneh tomb (the "Treasury") which boasts what is arguably the city's most spectacular and well-preserved facade (Fig. 1). A less spectacular northern approach is today used primarily as a utility road. Historically the city was approached by a number of routes from the north and west, as well as from the south, via a main route that passed Jabal Haroun (Aaron's Mountain).

In addition to its Nabataean and Roman history (on which most historical and archaeological attention has been focused), the site also saw prehistoric and Iron Age occupations and boasts later activity by Christian and Muslim populations alike. The Byzantine period is well represented today by three churches in the city center and a monastery complex on Jabal Haroun (Fiema and Frösen 2008). These include the cathedral of the Petraean see, the bishop of which participated in a number of history's important doctrinal councils (Fiema et al. 2001). Still later periods of occupation and use of the site are represented by two

Petra, Archaeology of, Fig. 1 At the end of the *Siq* visitors are greeted with a stunning view of the "treasury" (Al Khazneh)

crusader castles, a Mamluk period *weli* (shrine) to the Prophet Aaron on Jabal Haroun, a late medieval/early modern Islamic village at Bayda, and traces of Ottoman period habitation in the ancient tomb complexes. The areas surrounding Petra also boast a much broader history with evidence of activity from three hominid species extending as far back as the Paleolithic, as well as Neolithic and Bronze Age settlements (Kirkbride 1968; Byrd and Field 1989; Lindner & Genz 2000; Lindner et al. 2001; Jansson 2002; Vella et al. 2012).

Definition

Petra refers to an archaeological site in southwest Jordan that consists of an ancient city and its hinterland. The Nabataean people utilized the Petra valley from at least the mid-first millennium BCE prior to the full sedentarization of their culture. The earliest constructions in what would become the city of Petra likely began in the mid- to late third century BCE as the Nabataeans gained increasing control of the overland trade routes between the Arabian peninsula and the Mediterranean Sea. Petra became an important hub for ancient trade under the Nabataeans and continued in this role after the Roman annexation in CE 106. With the eventual collapse of the ancient trade networks that once sustained Petra's prosperity, the city became less prominent, and its character altered. Occupation at Petra continued following the Nabataean and Roman periods, including activity in the Byzantine and Islamic periods as well as a later Bedouin presence which lasted until quite recently. Archaeological evidence also suggests that prior to the monumentalization of Petra proper, human activity in the area extended well into prehistory.

Key Issues/Current Debates/Future Directions/Examples

Current Research and Future Directions

Since its reidentification by Swiss explorer Johann Ludwig Burckhardt in 1812, Petra has been the subject of many archaeological investigations. Excavations began at the site in 1930 and continue today, but the types of archaeological research have become much more diverse, expanding to include landscape surveys, geophysical investigations, GIS mapping, laser and photogrammetric documentation methods, and the development of conservation and preservation intervention strategies to help protect this fragile site and its environment. Following are examples of some of the major academic research projects active at the site today.

A number of interesting and important projects are affiliated with the Association for the Understanding of Ancient Cultures (AUAC), a nonprofit organization based in Basel, Switzerland. The International Umm al-Biyara Project, directed by Stephan G. Schmid (Humboldt University, Berlin) and Piotr Bienkowski (Manchester, U.K.), is a multidisciplinary exploration of the Nabataean monumental architectural remains on the summit of the flat-topped Umm al-Biyara mountain, which has sometimes been described as the "acropolis" of Petra. Several seasons of mapping and test excavations have demonstrated that these are possibly the remains of a royal or other elite complex situated to overlook the Petra city center. The International Aslah Project (IAP), directed by Robert Wenning (University of Münster) and Laurent Gorgerat (Antikenmuseum Basel und Sammlung Ludwig), is investigating one of the most important rock-cut cultic areas in Petra. The research area is focused around the monument known as the Aslah Triclinium, which contains what may be the oldest, dated Nabataean inscription known at present. Employing both survey and excavation methods, the project has yielded one of the best data sets yet available to help understand the role and functions of the many shrine installations found around the ancient city. The North-Eastern Petra Project (NEPP), directed by Stephan G. Schmid, Zbigniew T. Fiema, and Bernhard Kolb, is a landscape and architectural survey that began recently of an important but largely unexplored sector of the city center near the monument known as the "Palace Tomb." This project is undertaking a detailed mapping of the freestanding architectural remains in the area, employs some geophysical investigations, and hopes to eventually excavate some of the features.

Several projects are currently working to expand our understanding of the funerary

landscape of Petra which, although seemingly apparent due to the prevalence of the tomb façades, actually remains quite obscure. Two projects directed by Lucy Wadeson (Oxford University) and affiliated with the AUAC, the International Khubtha Tombs Project (IKTP) and the Funerary Topography of Petra Project (FTPP), both seek to elucidate aspects of the funereal practices in the city. The IKTP is scientifically excavating the areas inside and outside selected tombs and the FTPP is investigating the possible functional relationships between these spaces. Another set of tomb excavations directed by Isabelle Sachet and Natalie Delhopital, in association with the mission archéologique français de Pétra (MAFP) of the Centre national de la recherche scientifique (CNRS), have yielded additional information about funerary spaces and, most importantly, uncovered some of the first stratified burial deposits to augment the limited data from previous excavations in disturbed tombs (Bikai and Perry 2001).

The Petra Garden and Pool Complex (PGPC), directed by Leigh-Ann Bedal (Pennsylvania State University – The Behrend College, Erie, PA), has been investigating a unique set of water installations and gardens that are situated in the heart of the city center (Bedal 2003; Bedal et al. 2007). The results from this project have contributed to a better understanding of the central urban fabric of the city and raised intriguing questions about the possible symbolic roles played by the control and display of water in this arid landscape.

Brown University in Providence, RI (USA), has sponsored two major field projects. The first is directed by Martha Sharp Joukowsky at the "Great Temple" complex in the city center (Joukowsky 1998, 2007). The second, the Brown University Petra Archaeological Project, directed by Susan E. Alcock and Christopher A. Tuttle, is aimed at gaining a diachronic understanding of the relationship of the city to its hinterland. This project is composed of several different components, including limited excavation and geophysical prospection in the city center itself. The bulk of this project's activity, however, has focused on the site's hinterland to the north, through a combination of highly intensive pedestrian survey, architectural recording and mapping, geophysics, and strategic excavation probes, as well as more extensive excavation at the Islamic village at Bayda. Results point to an enormously rich artifactual landscape and one much modified, over the millennia by human activity (Alcock and Knodell 2012).

The major long-term project of the MAFP, directed by Christian Augé (CNRS), is the investigation of the "Qasr al-Bint," a Nabataean temple in the city center, which is the only freestanding building to survive largely intact to the present day. This French project has produced the definitive architectural study of this important building and, through excavations in its precinct, has elucidated different aspects about the uses of civic cultic space in the city throughout different historical periods.

The search for "Early Petra" is a major research initiative involving a number of different projects. These efforts are seeking evidence of the earliest Nabataean-constructed environment in the Petra valley, hints of which were first revealed by excavations in the 1950s (Parr 1957, 1960). The Hellenistic Petra Project, directed by David Graf (Miami University) and Stephan G. Schmid (Humboldt University, Berlin) has conducted several seasons of excavation in areas adjacent to Parr's original trenches in order to verify and elucidate the original published data (Graf et al. 2005, 2007). Additional work on "Early Petra" has been undertaken as part of the MAFP, also in the vicinity of the Qasr al-Bint (Mouton et al. 2008). These projects have collectively now proven that there was a constructed environment in the mid- to late Hellenistic period in the Petra city center, although a complete understanding of the full nature and extent of these constructions still awaits additional research.

Despite the nearly 200 years of documentation now completed in Petra, potential for future research in the archaeological park remains enormous. Technology has offered exciting ways to investigate Petra and further our understanding of this important site. The trend in archaeology toward nondestructive investigations has taken hold in the ancient city. For example, the use of geophysical and remote sensing techniques has

already started to tell us more of what lies beneath the accumulations of time (Conyers et al. 2002; Urban et al. 2012). We can anticipate that through the judicious employment of both new and old methods, the wonders of Petra will continue to astound for many generations to come.

Threats

As with many World Heritage Sites, Petra's popularity has been a mixed blessing, with tourists making substantial contributions to the host economy but also posing a serious threat to the preservation of the site (see Comer 2012). The sprawling site is difficult to police, and visitors routinely climb and walk on architectural features and remove artifacts as souvenirs. The Bdoul Bedouin tribe that once resided inside Petra and many of its monuments was ejected in the 1980s as part of the process for establishing the World Heritage Site and associated park. Many were displaced to the nearby village of Umm Seyhoun. Many Bedouin now earn a living providing guide services and running small tourist shops in the city center. Others have found work with archaeological teams providing field assistance and logistical support to research at Petra. There also seems to be a general problem with looting, with artifacts spanning the full occupational history of the region readily available for sale to tourists at the shops. While necessary for sustaining the economic survival of the local Bedouin, these different types of engagements with the archaeological park also create threats to the site as the result of inadequate management and mitigation strategies. Efforts are presently underway to develop appropriate and sustainable strategies that will hopefully ameliorate some of these potential threats.

In addition to human pressures, Petra also faces much natural erosion due to the action of wind and water. Recently, for example, a Byzantine church in Petra's city center has sustained water damage to its floor mosaic (Fig. 2). Some of the most significant threats faced by Petra are those related to conserving and preserving the monuments carved and constructed from the fragile sandstone. All of the monuments are endangered through human and animal interactions, water, wind, solar radiation, and salt efflorescence from the building materials themselves. Neither a coherent conservation management plan nor a trained team of conservation technicians exist in the park to undertake sustainable preservation interventions. Despite these limitations, substantial progress in improving the situation has been made in the past several years.

The UNESCO office in Amman, Jordan, in partnership with the Petra Development and Tourism Regional Authority (PDTRA) has recently completed the definitive GIS mapping of the Petra Archaeological Park boundaries, which encompass some 264 km^2. This effort has also

Petra, Archaeology of, Fig. 2 The Byzantine Church in Petra's city center exhibits spectacular floor mosaics which are presently threatened by water damage

produced a proposal for the creation of the associated buffer zone that is required for a World Heritage Site. The UNESCO team also pioneered a new methodology for risk mapping and categorizing, assessing, and prioritizing the various threats to the site.

Several current projects are aimed at addressing the need for developing sustainable conservation capacity and practices. The Petra Archaeological Park is presently designing a conservation management plan that will define priorities and lay the foundation for establishing a set of policy and procedural standards. The Petra National Trust is undertaking the Wadi al-Jarra Dam Restoration Project that is working to rehabilitate ancient Nabataean water management installations to help control flood waters near the Al Khazneh monument. The American Center of Oriental Research (ACOR) is executing two major preservation projects, the Petra Church Maintenance and Restoration Project and the Temple of the Winged Lions Cultural Resource Management Initiative. Both of these projects are designed to implement urgent interventions to preserve the respective monuments but also involve technical capacity building in the local communities as a means of creating a trained workforce to facilitate making future conservation initiatives sustainable.

Basic Biographical Information

William Matthew Flinders Petrie was born on 3 June 1853 in Kent, England. The only child of a middle-class Victorian family, his father William Petrie was an inventor and surveyor, while his mother Anne was the only daughter of famed explorer and navigator, Matthew Flinders. After a severe childhood illness almost claimed his life, Petrie's parents were advised to restrict his contact with other children to avoid any further risks to his health. As a result, Petrie never attended a formal school and was instead homeschooled by his mother; by 10, Petrie had taught himself chemistry and minerology (Drower 1985: 15–17). As a child and young teenager, his parents took him on many family holidays to measure and survey ancient British monuments, and this provided Petrie with a solid foundation in surveying and recording techniques. In 1874, Petrie and his father surveyed Stonehenge for the first time and completed the study by June 1877; after which young Petrie set off alone to survey British ancient earthworks between 1875 and 1880, developing a survey methodology he would employ for the

rest of his life (Drower 1995: 22–24). At the age of 24, Petrie undertook his only formal education with a university extension course in algebra and trigonometry (Drower 1985: 18). In 1880, he began his survey of the pyramids at Giza in Egypt. For the next 44 years, Petrie continued his work in Egypt, accompanied by his wife Hilda, whom he had married in 1896. In 1923, Petrie was honored with a knighthood for his services to the field of archaeology. In 1927, he moved his excavation efforts across the Egyptian border into Palestine. He continued this work for a further 11 years. Flinders Petrie died in the British Mandate of Palestine on 28 July 1942, at the age of 89.

Major Accomplishments

Flinders Petrie pioneered many revolutionary techniques in the field. He is often referred to as the "Father of British Egyptology" (Persson 2012: 9). Petrie's exposure to rigorous surveying methods as a child is evident in his later career as an archaeologist. His first expedition to Egypt (1880) was to begin his detailed measurement and survey of the pyramids at Giza. At Tanis (1884), Petrie implemented his new, systematic approach to excavation. He instructed his team to excavate the site in a systematic fashion, focusing on the various layers within the site and their relationship to each other (Encyclopedia of World Biography 2004). This was an approach that was not utilized by other archaeologists at the time. Rather, Petrie's contemporaries would extract the interesting or unique pieces that they found with no reference to the chronology of the site or the context of the find.

Throughout his extensive career, Petrie discovered some extraordinary Egyptian artifacts, such as a collection of jewelry dating to the twelfth dynasty. Furthermore, Petrie uncovered the physical records of the first two dynasties of the Egyptian civilization, which had originally been thought to be mythical, as well as inscriptions of an early alphabet in a Middle Kingdom temple and the famed Merneptah Stele near Thebes, discovered in 1896 (Drower 1995: 221; Drower 2012: 3–4). Petrie also had the honor of discovering the Greek colony of Naukratis in Egypt in 1885 near Giza (Petrie 1990). Despite these great discoveries, at sites Petrie also insisted on recording and excavating more mundane objects, particularly sherds of undecorated pottery, that were previously ignored in the search for rare and exotic artifacts. This practice allowed Petrie to develop the concept of "sequence dating," a method also known as "seriation." He further extended this by developing a "cross-dating" technique that facilitated the use of Egyptian artifacts to date strata at other sites outside of Egypt (The Columbia Encyclopedia 2012). Moreover, he strongly believed that assemblages uncovered together had to remain together as he regarded splitting them as destroying essential contextual information that a full assemblage provided (Sparks 2013: 157).

Petrie's greatest contributions to the discipline of archaeology were made in the field. As well as systematic excavation techniques and seriation, Petrie was known for his obsessive recording of detail, a practice that stemmed from his adherence to the concept of scientific observation. Petrie also argued that records should be supplemented with pictures, diagrams, and plans to make sites easier to study, especially if they were destroyed during the excavation (Petrie 1904: 114). Moreover, he stated that it was an "unpardonable crime" in archaeology to excavate carelessly and not make written records and plans of the excavation (Petrie 1904: 48). While his field methods were heralded as revolutionary for his time, Petrie's theoretical interpretations of the results he obtained were (and in some cases, still are) considered to be highly controversial. His theories on the origins and development of the alphabet were strongly opposed by his contemporaries, while his connection to noted eugenicist Francis Galton has drawn criticism from subsequent generations of archaeologists (Encyclopedia of World Biography 2004; Sheppard 2010). Moreover, he was criticized for creating an "impossibly long" chronology for ancient Egypt as well as applying eugenics theory to that work (Drower 2012: 5; Sheppard 2010: 19–20, 22). In contrast to his expertise in excavation and classification, his survey techniques were considered by his peers to be rudimentary

(Gardiner 1942: 204). However, Petrie's shortcomings have been defended as he "[fought] with the weapons that he knew or himself invented" (Wheeler 1953: 91). It should be remembered that when Petrie began his work in the 1880s, very few of his contemporaries were as committed to detail or interested in the things which are considered essential today.

Despite having had very little formal education, Petrie's academic career was outstanding. In 1892, he was made the first Edwards Professor of Egyptology at University College London (UCL). He retained this position until 1933, and the Egyptian Archaeology Museum at UCL is named in his honor. Additionally, his career in the field was extensive. Beginning in 1875 in Britain, he began his work in Egypt in 1880. He continued there until 1924, and in 1927 he moved his excavations across the border in to Palestine. His work in Palestine continued until 1938, and he remained in the country until his death 4 years later. Obituaries and postmortem accounts of his life highlight a pioneer of modern, scientific archaeological methods (Gardiner 1942: 204; Wheeler 1953). Arguably, the best summation of Petrie's career is that he "found Egyptology a treasure hunt, and left it a science" (Drower 2012: 5).

P

Phenomenology in Archaeology

Ruth M. Van Dyke
Department of Anthropology, Binghamton University, Binghamton, NY, USA

Introduction

Phenomenology in archaeology refers to an interpretive method and associated theoretical stance developed by British post-processualists. Most phenomenological research focuses on investigations of past landscapes. Phenomenological archaeology draws its theoretical position and its inspiration from the existential philosophy of Edmund Husserl and Martin Heidegger. It is based on the assumption that there are universal

similarities in human spatial perception. Because all human bodies share the same configuration, we can assume that all humans have generally similar spatial perceptions of such body-relevant experiences as directionality and scale. The human body organizes spatial experiences into up and down, front and back, and left and right. And, like us, past subjects constructed their spaces to create and reflect aspects of their habitus. If we accept these premises, then a phenomenological approach can give us insights into the ways in which prehistoric peoples experienced, perceived, and represented the spatial world. Phenomenological archaeologists work from the starting point of contemporary bodies in the same spaces, moving through ancient landscapes and architecture as prehistoric peoples did. Proponents assert that the judicious employment of phenomenological methods aids archaeological investigations of past meanings, worldviews, and emotions. Phenomenology helps humanize the past and has inspired new research into the senses and the body. Critics focus on empirical as well as epistemological issues, contending that phenomenological approaches do nothing to advance archaeological knowledge. The debate is itself a healthy development for the discipline.

Historical Background

Phenomenology in archaeology derives from phenomenology in existential philosophy. Gosden (1994), Casey (1996), and Thomas (1996) all provide good reviews of this intellectual history. Existential philosophy addresses the realism v. idealism conundrum that Western philosophers have pondered since Plato. Paradoxically, we know the world by separating ourselves from it, but at the same time, we can only understand ourselves in relation to the world. So, to what extent is the world "real," and to what extent is it a construct of our consciousness? Rene Descartes' (1641) solution was "I think, therefore I am." Immanuel Kant (1781) distinguished between the "phenomenal" world, or the world as our consciousness apprehends it through the filters of our senses, and the "noumenal" world, or an objective reality that remains beyond the grasp of our imperfect bodies and minds. Following these thinkers and the work of the nineteenth-century philosophers Søren Kierkegaard and Friedrich Nietzsche, existentialism posits that we bridge the distance between objective reality and our subjective consciousness through existence or daily experiences and participation in the world. Phenomenology – one branch of existentialism – emerged in the twentieth century through the works of Edmund Husserl (1931), Martin Heidegger (1927), and Maurice Merleau-Ponty (1962).

Husserl argues that we know the world not through pondering it (à la Descartes) but rather through daily life, experience, and perception. Conscious, intentional, bodily engagement with the physical world is the starting point for all knowledge. Husserl is an idealist – for him, understanding the world hinges around these shared, conscious *perceptions* of experience. Heidegger, a student of Husserl, moved the conversation away from epistemology (the study of how we know what we know) towards ontology (the study of being or existence). Like Husserl, Heidegger sees the human body as the point of dialectical mediation between consciousness and the physical world, subject and object. However, for Heidegger, bodily experience takes precedence over ideals and intentions, because experience creates the context in which all else takes place. Existence involves a mesh of contingent relationships with other beings and objects in both a spatial and temporal dimension. Place has a critical part to play for Heidegger – all bodily experiences are spatially situated. This is explored in Heidegger's concept of *Dasein*, translated as being-in-the-world or dwelling (see Thomas 1996 for a good discussion). Maurice Merleau-Ponty (1962) further elaborated upon these ideas, focusing on the intersections between the body, perception, consciousness, and place.

Phenomenology resonates well with practice theory, as both are concerned with breaking down a subject/object or actor/structure dichotomy, refocusing attention on the ways in which understandings, meanings, and actions are mutually constitutive. Bourdieu's concept of habitus has synergy with Heidegger's *Dasein*, as

meanings arise through lived, daily, bodily experiences. The hermeneutic or dialectical aspects of these approaches have common Marxian roots (see Gosden 1994: 113–122). Both phenomenology and practice theory contributed to the development of humanistic geography, with its focus on place and landscape (see Tuan 1974, 1977; Cosgrove 1984; Jackson 1984; Lefebvre 1991; Casey 1996, 1997, 2001; Soja 1996).

Archaeological Cases

Given this history, it should come as no surprise that existential philosophy, practice theory, and humanistic geography have contributed to the emergence of a landscape archaeology that sees place as a mutually constitutive part of the social and spiritual world rather than as a set of resources to be objectively exploited (see, e.g., Bender 1993; Bradley 1998; Ashmore and Knapp 1999). However, not all landscape archaeology is phenomenological nor is all phenomenological archaeology focused on landscape. All phenomenological archaeologists share the view that we make sense of the world by experiencing it. Some go further to contend that their own bodily perceptions can provide a means for learning about the past. By the early 1990s, British archaeologists began to explicitly explore the relevance of Heidegger's phenomenology for archaeology (Ingold 1993; Gosden 1994; Tilley 1994; Thomas 1996).

Tim Ingold (1993) starts from Heideggerian *dwelling-in-the-world* to build his concept of *taskscape*, which adds temporality and practice to the spatial study of landscape. Ingold points out that people are never disembodied, but move seamlessly through the world and through time. Meaning is created and sustained through cross-cutting fields of relationships among people, objects, and places that gradually unfold. *Tasks* – the practical activities carried out by people on a daily basis – are the constitutive acts of dwelling. The *taskscape*, then, is an inherently social array of spatially and temporally related activities.

Thomas (1996) employs Heidegger in a sophisticated critique of archaeological practices that are, he contends, mired in Descartian dichotomies. Archaeologists tend to objectify the material record as a target of study, or we try to read it as a text, but neither really works. We need to break down the false separation between human existence and the material. *Dasein*, or being-in-the-world, encourages us to think of objects, meanings, places, and people as continually, mutually constitutive, flowing into one another across time. Thomas illustrates the differences between phenomenological and objectifying approaches using three British Neolithic case studies, each at different scales. For example, objectifying approaches interpret a chambered tomb in Wales as a transcendental expression of structural meaning. From a dwelling perspective, by contrast, the chambered tomb is one in a chain of performative events linked with recent and older ideas and practices.

In *A Phenomenology of Landscape*, Christopher Tilley (1994) set forth a program for phenomenological landscape archaeology that has inspired a host of emulators and has sparked energetic critique. Archaeologists, Tilley argued, generally objectify landscapes, viewing places as empty, abstract containers for resources and actions. Tilley contrasted this "space as container" perspective with the human, bodily experience of places as meaningful, spiritual, temporal, and corporeal. He grounded his theoretical position in Heidegger's concept of dwelling and then tied phenomenology into concurrent, overlapping development in practice theory, humanistic geography, and Native American cultural landscapes (see, e.g., Basso 1996; Cosgrove 1984). Following Merleau-Ponty and de Certeau, Tilley is interested in how people construct and experience places by moving through them; he defined landscape as relational places linked by paths. Tilley believes that archaeologists' own bodily experiences as they walk through landscapes can be a source of information about the past. He expanded phenomenology from a philosophical framework for interpretation to a methodological approach.

Tilley carried forward his ideas through a series of case studies. The second half of his 1994 book featured narratives about Tilley's phenomenological perambulations through the British prehistoric countryside, conveyed through thick description and photographs. He focused on the

viewsheds of high places and monuments and on the order in which places are experienced as a walker moves among them. He is also interested in the ways built places can evoke natural features and the ways in which topographies affect bodily experience (such as difficulties in climbing steep hills). Tilley followed *A Phenomenology of Landscape* with additional volumes (Tilley 2004, 2008, 2009) in which he further developed his philosophical position and presented additional case studies. In these works, Tilley moved beyond the British Isles to investigate Breton menhirs, Maltese temples, and Scandinavian rock art. He expanded his solitary musings to incorporate the observations of earlier researchers, and he argued for synesthesia, or the involvement of all the senses in bodily experiences. For example, on Malta, Tilley (2004) suggested particular limestones were associated with honey and the sweet smell of death, while other limestones were associated with ochre and the living. Tilley's work has inspired a small but enthusiastic cadre of phenomenological practitioners in archaeology.

Among the best known of these is the work of Vicky Cummings and colleagues on the megalithic landscapes of Neolithic Wales (Cummings et al. 2002; Cummings and Whittle 2004). Like Tilley, Cummings et al. adopted an explicitly phenomenological framework and focus on the role of vision in the perception of place. Cummings et al. conveyed the bodily, experiential qualities of Neolithic tombs and monuments using thick descriptions of the features in their topographic settings, supplemented by photographs. The authors wanted their observations to be replicable, and so they made considerable effort to systematically record their visual observations, drawing and photographing 360° panoramas around each monument, and employing GIS to explore viewsheds. Cummings et al. argued that Neolithic monuments in Wales both concealed and emphasized particular vistas and topographic features. Chamber tombs, for example, are situated at places where viewsheds change. Ultimately, the authors used their phenomenological observations to bolster structuralist interpretations. For example, they argued that chamber tombs spatially evoked a transition from symmetry to asymmetry and back to symmetry, mimicking three stages of a human body as a living entity, a decomposing corpse, and a set of skeletal remains.

Similarly, Van Dyke (2007, 2011) conducted a phenomenological analysis of the monumental landscape of Chaco Canyon in the Southwest United States. Focusing on viewsheds and visibility, Van Dyke walked ancient routes into Chaco Canyon, using a video recorder, still photographs, and thick description to convey her bodily experiences. Van Dyke found a series of nested dualisms or oppositions illustrated by monumental architecture and by the placement of these buildings in dramatic topographic settings. She argued that Chacoan builders intentionally designed a spatial experience to legitimate their power for pilgrims to this "center place." Van Dyke supported her essentially structuralist interpretations with indigenous Pueblo ethnography and ethnohistory.

Hamilton and Whitehouse (2006) were among the first to move phenomenological work beyond visual perception and monumental architecture. They investigated Neolithic sites identifiable as artifact scatters in plowed fields in northeast Italy. Hamilton and Whitehouse incorporated sound, smell, and gendered bodily differences into their research. They worked to develop explicit, replicable phenomenological methods. Like Cummings and her colleagues, they drew 360° panoramas from the center of each site, recording near and distant landmarks and horizons. Hamilton, Whitehouse, and their team systematically walked out and back from sites over set periods of time, periodically recording observations. They conducted experiments to identify distances for different kinds of intervisible interactions (e.g., signaling v. presence of a human form) and vocal interactions (normal speech v. shouting). Hamilton and Whitehouse noted gendered differences along all of these dimensions. Their work is a significant contribution towards a phenomenological methodology.

Current Debates

Human beings do not experience spaces as abstract, empty containers. Phenomenology in archaeology arose as one way to transcend the

sterile, objectifying, treatment of landscapes in more traditional methods such as settlement pattern analysis or catchment analysis. Advocates contend that phenomenological approaches help archaeologists to think about past peoples' meaningful, memory-laden, emotional, sensory, and metaphorical connections with their surroundings. For archaeologists using practice theory, in which people and their worlds are mutually, continually engaged, phenomenology provides a method for investigating those reflexive constructions.

Nonetheless, the critics of phenomenology in archaeology are many and vocal. Major appraisals to date include Joanna Brück's (2005) measured assessment, Andrew Fleming's (1999, 2005, 2006) scathing dismissals, and John Barrett and Ihlong Ko's (2009) philosophical analysis. Criticisms may be roughly grouped into two categories – those that focus on faulty or incomplete methods and analyses and those that revolve around larger questions of ontology and epistemology. In the first set of criticisms, scholars have argued that phenomenological archaeology lacks replicability and methodological rigor, fails to contend with past/present environmental differences, ascribes a monolithic universality to bodily experience, fails to acknowledge that experience is culturally constructed, privileges the visual, and emphasizes description at the expense of power relations. In the second group of criticisms, scholars have pointed out that phenomenological archaeology has a tendency to devolve into structuralism, represents a misuse of Heidegger (who was, furthermore, a Nazi sympathizer), conflates association and causation, and lacks epistemological legitimacy. Many of these critical points – particularly those in the first batch – have merit and should lead phenomenological archaeologists towards stronger interpretations. Other criticisms – particularly those in the second group – are grounded in fundamental epistemological differences among researchers and, thus, are unlikely to be resolved.

Faulty or Incomplete Methods and Analyses

Phenomenological interpretations originate with the subjective experience of the researcher. The researcher's bodily experience is meant to provide her with insight into the intentions of past builders. But in order for a credible body of knowledge to be constructed, the subjective researcher's bodily experience should be replicable by others. Fleming revisited some of Cummings and Whittle's megalithic sites and did not see what they saw, leading him to conclude that phenomenology does not constitute a legitimate epistemological method. Rather, Fleming argues that phenomenologists produce nothing more than the researchers' own contemporary, romantic perceptions of contemporary landscapes. Hamilton and Whitehouse concurred with Fleming that phenomenology needs replicability and methodological rigor. They developed a set of standardized forms for researchers to use in recording phenomenological observations, and they carried out work in teams rather than as solitary walkers.

Clearly, the archaeological landscapes of today are not identical to the cultural landscapes of the past, even when there is relatively good architectural preservation. Phenomenologists should take into account changes in vegetation, weather, seasons, and architecture. Nonetheless, past landscapes no longer exist – contemporary landscapes can only provide researchers with partial, distorted experiences. Just as the landscape is not constant, neither is the human body. Phenomenology proceeds from the assumption that bodily experiences of landscape are to some extent universal, but bodily experiences surely would have been dissimilar for individuals of different ages, genders, and social standings. Hamilton and Whitehouse engaged with this point through their work on Neolithic ditched enclosures in Italy. Rather than assuming a universal (and by default, male) human body, they explicitly incorporated and recorded gendered differences in bodily movement and perception.

But even if bodies, topographies, and features could be held constant, spatial experiences are – as Bourdieu has taught us – culturally constructed. Although human bodily configurations are to some extent always shared, past sensual perceptions were culturally situated and might be quite different from our own. For example, phenomenological accounts are often written from the

perspective of the solitary walker encountering the past for the first time – but past meanings were created and negotiated by people as participants in social worlds engaged in repeated, multiple encounters with places.

Although phenomenologists claim to engage with bodily experience, in practice their work has focused almost exclusively on the sense of vision, revolving around intervisibilities among monuments, or shifting visual perceptions along routes of movement. This is shifting somewhat – Tilley's more recent work incorporates smell and touch. Hamilton and Whitehouse carried out a series of acoustic experiments using different sounds and less systematically noted the presence of various smells. New work in sensory archaeology (e.g., Hamilakis et al. 2002; Day 2013) moves well beyond the visual, monumental landscapes favored in early case studies.

Phenomenological explanations essentialize description to the detriment of explanation, privileging the sensory over the political (Smith 2003: 67–68). Phenomenologists often argue that buildings or landscape elements represent certain ideas, for example, but fail to give their attention to the social and political processes through which these symbols were negotiated. Although power may be an underdeveloped dimension of some phenomenological studies, researchers are well aware that spaces are political (e.g., Tilley 1994: 20–21). Van Dyke, for example, explicitly argued that spatial experiences on the Chacoan landscape were meant to legitimate the power of ritual elites.

Finally, critics contend that phenomenologists lack the means to distinguish between association and causation. Phenomenologists may observe sensory regularities (such as intervisibility with a particular mountain peak), and those observations may be replicable, but this association does not demonstrate that the regularities were meaningful to ancient people. Mountain peaks are tall and are visible from many places. This methodological problem is closely tied with a larger, epistemological issue.

Ontological and Epistemological Objections

The descriptive cast of many phenomenological interpretations emerges from a latent structuralism common to most analyses, including those of Tilley, Cummings, and Van Dyke. Fleming considers that the ancient dualisms identified by phenomenologists are created by the scholars' own modernist worldviews. But even if past peoples did situate architecture to embody structural dualisms, to what extent were these meaningful? Were they intentional? Is a transcendental, abstract, structuralist perspective at odds with a philosophy that posits meaning as created through immediate, participatory, bodily experiences? At the crux of this group of criticisms are fundamental anthropological and philosophical questions about the nature of social meaning and the construction of knowledge. One question has to do with Heidegger's politics.

Heidegger was a member of the Nazi party from 1933 to 1945. For many scholars, this does not detract from the power of his ideas, whereas for others, it is a damning indictment that renders his work ethically unpalatable. Some archaeologists contend that because a scholar's ideology is not separable from his/her thoughts and writings, Heidegger's work is not separable from the fascist ideals he believed in. However, the phenomenological issues Heidegger investigated are part of a philosophical tradition that transcends Nazism. Husserl – his mentor and a major phenomenological philosopher – was, in fact, a Jew by birth, who lost his academic position under the Nazi regime.

Barrett and Ko's (2009) address another problem with archaeologists using Heidegger. Barrett and Ko contend that phenomenological archaeologists have misread the philosopher and would do better to ground their work in Husserl. Their argument may be summarized as follows. For Heidegger, human understanding of the world arises through subjective, experiential encounters, or *zuhanden*. Humans can also construct knowledge through *vorhanden*, or intentional, objectifying inspection, but *zuhanden* creates the context of knowledge and thus must come first. Husserl, by contrast, contends that humans must detach from the world in order to learn about it. Husserlian phenomenology emphasizes conscious and intentional experience. Barrett and Ko (2009) point out that British phenomenologists assume an ahistorical, transcendental vantage point. They treat the

knowing subject as conscious and objectifying, thereby privileging *vorhanden* rather than *zuhanden*. Thus, phenomenology as practiced by such scholars as Tilley, Cummings, and Whittle is really Husserlian rather than Heideggerian.

Barrett and Ko argue that Tilley, Cummings, and Whittle's works contain unstated, problematic premises about ancient builders' intentions. Phenomenological archaeologists have assumed that human action is goal oriented and that monument builders sought to ensure certain visual consequences. Thus, the archaeologists believe the monuments allow them to access the builders' motivations. However, for Heidegger, landscapes and monuments do not inscribe a cultural order – rather, dwelling is an act of engagement with the world, and order is emergent. Top-down structural analyses would appear to be at odds with *Dasein*.

So, are contemporary archaeologists' experiences a legitimate source for interpretations about the past? Barrett and Ko argue that they cannot be, unless we invoke the transcendental universals that are anathema to a Heideggerian phenomenology. Barrett and Ko are correct that analyses that offer nothing more than structuralist descriptions are incomplete and more Husserlian than Heideggerian. But this does not negate the value of phenomenological studies for identifying sensory patterns in the material world. This criticism is really a restatement of a fundamental anthropological question about the relationship of agency and structure.

Barrett and Ko conflate the identification of transcendental patterns with the investigation of a deeper question – to what extent are these patterns intentionally constructed, agenda-driven order, and to what extent are they emergent, nondiscursive properties? The relationship between agency and structure is important for understanding ancient political and social order. But before archaeologists can interpret past social worlds, they must first identify patterns that allow them to build interpretations. Phenomenological archaeology provides one means for identifying sensory patterns that may be both discursive and nondiscursive in origin.

Those researchers who do not consider interpretive approaches as valid pathways to archaeological knowledge see phenomenology as at best naïve, at worst a threat to archaeological authority. For archaeologists such as Tilley who consider the past to be constructed within a political present, this is less of an issue. All we have, ultimately, is our own culturally situated understandings of the past – we cannot "access" the "true" past. However, this position threatens the authority of archaeologists as singular arbiters of knowledge about the past, leading some to consider phenomenology as quite dangerous (witness the vitriol in Fleming's attacks). The crux of the dispute is epistemological – what are the acceptable avenues by which we can construct knowledge? Philosophers have been struggling with this question from Plato and Aristotle onwards, so it is unlikely that archaeologists will resolve it any time soon.

Future Directions

The full potential of phenomenology in archaeology has yet to be realized. The introduction of explicitly phenomenological approaches in archaeology is giving rise to several positive developments. In general, there is more of a concern with visual perception and meaning than there has been in the past. Archaeologists are likely to think about lines of visibility from shrines on high places to dramatic, distant peaks, and they are likely to ask questions about whether these connections could have been meaningful in the past (e.g., Boivin 2004). Following Hamilton and Whitehouse, archaeologists are more aware of gendered and other bodily differences in spatial experience, and they are likely to think about how bodies experience movement across different kinds of topographies (e.g., Scarre 2002). They are conducting systematic experiments to assess differences in movement, sound, or sight across landscape. Increased methodological rigor should help to bolster the perceived legitimacy of phenomenological approaches in the eyes of some critics. These explorations are connected to a burgeoning interest in sensory and haptic archaeologies concerned not just with the visual but also with sound, touch, taste, and smell (see, e.g.,

Gosden 2001; Watson and Keating 1999; Hamilakis et al. 2002; Day 2013). Finally, a great value of phenomenological archaeology is that it challenges scholars of all theoretical persuasions to engage with deeper ontological and epistemological questions.

Phillips Spring: Agriculture and Domestication

Marvin Kay
Department of Anthropology, University of Arkansas, Fayetteville, AR, USA

The Phillips Spring site (23HI216), discovered in 1973, is within the Pomme de Terre River valley in northern Hickory County, Missouri. The drainage is part of the larger middle Osage River basin that empties into the Missouri River. The Pomme de Terre is familiar to Quaternary specialists as the location of Albert C. Koch's 1840 excavation of the American mastodon and its claimed association with artifacts. More recent investigations, beginning in the mid-1960s, have reevaluated Koch's find as well as examined deeply buried, multilayered sites, among them Rodgers Shelter and Phillips Spring. Systematic excavations of Phillips Spring, an active artesian spring, began in 1974 and continued in the years 1976–1978. The initial investigation (Chomko and Crawford 1978) attempted to locate another late Pleistocene (ca. 40,000–11,700 calendar year b2 k [before AD 2000]) or Holocene (since 11,700 calendar year b2 k [before AD 2000]) (Walker et al. 2009) palynological record that might coincide with the prehistoric habitations in the valley and to provide direct evidence of middle Holocene environmental and climatic conditions in the western Ozark Highland. Ultimately, these goals were largely satisfied. Along the way, even more impressive discoveries were made, including that of potential ancient cultigens (*Cucurbita pepo* [pepo "squash"] and *Lagenaria siceraria* [bottle gourd]). The unimpeachable, deeply stratified contexts of these Phillips Spring discoveries extended the record of plant husbandry for the Archaic of the Eastern Woodlands of North America to a date earlier, in radiocarbon years, than 2250 B.C. (4200 years B.P.). One pepo seed fragment came from alluvium dating about 7000 radiocarbon years ago (5050 B.C.); however, the earliest pepo and bottle gourd seed and rind concentration is younger and dates in radiocarbon years from 3050 to 2250 B.C. (5000–4200 B.P.). These discoveries were a catalyst in reformulations of the Archaic as a period of dynamic adaptation and experimentation with both exotic and local plant resources.

The site is now recognized as the earliest (Smith 1992, 2011) of the Eastern Agricultural Complex (EAC) of North America and the first example of domestication of pepo squash dating to at least 5000 calibrated radiocarbon years ago. Other early EAC representatives are Napoleon Hollow in west Central Illinois, Riverton in east Illinois, Cloud Splitter and Newt Kash in northeast Kentucky, Hayes in Central Tennessee, and Marble Bluff in Northwest Arkansas. Phillips Spring shares with Napoleon Hollow a general cultural identity as part of the Sedalia, Titterington, and, in the Kansas City area of Missouri, Nebo Hill complexes. Explanations of the EAC as an independent center of plant domestication divide into landscape constraints on plant domestication and human population pressure (Smith 2011; Weitzel and Codding 2016). Their physiology, prodigious seed production potential, and ability to propagate without much if any

human intervention (Smith 2011) may well have favored cucurbits to early domestication, especially when combined with moist habitats near active artesian springs. Population pressure is not inconsistent with this notion either, as early to mid-Holocene archaeology records a progressive increase likely causing greater stress on natural food resources (Weitzel and Codding 2016). Under such conditions gardening cucurbits would have been a low-risk/high-return strategy. Undoubtedly, these and other theories will continue to be assessed, as they have now assumed a life of their own.

Phillips Spring is a deep, finely stratified archaeological site with exceptional preservation of normally perishable, not carbonized plant remains. Under these sediments is an equally important, older alluvial record for the late Pleistocene and early Holocene that contains scattered pollen layers. Its remarkable organic preservation stems from the anaerobic environment created by the spring itself. The site contains the best-defined, radiocarbon-dated sequence of Holocene alluvial cut-and-fills in the valley. Just above bedrock is a Late Wisconsin Boreal Forest assemblage dominated by jack pine that dates to ca. 25,350 R.C.Y.B.P. (23,400 B.C.). Unlike other artesian springs in the valley (Haynes 1985), Phillips does not contain a Pleistocene bone bed.

The archaeology of Phillips Spring is dominated by Late Archaic Sedalia phase (ca. 2550–650 B.C. or 4500–2600 years B.P.) encampments that probably represent base camps (Haynes 1985; Kay 1983, 1986; Kay et al. 1980). Subterranean food storage facilities were dug, and large, oval basins were used as steaming pits for communal cooking. The most common food species represented are pepo and the exotic tropical cultigen, bottle gourd, plus native plants among which walnut, hickory, and oak acorns figure prominently (King 1985; see also Chomko and Crawford 1978; Monaghan et al. 2006). Most of these species would have been grown, collected, and stored during the summer and into the fall. Seed and rind morphology of pepo and bottle gourd suggests their growing may have been either for their seeds, as containers, or both. Storage pit construction and use was mainly a summer-fall operation, which could well have continued into the winter or early spring. Adzes dominate the tool assemblage, but simple groundstone tools and a variety of hafted chipped-stone points are present, too. The adzes have been referred to as "Sedalia diggers," but they are clearly heavy-duty woodworking tools. At least one broken Nebo Hill lanceolate of seemingly nonlocal material (presumably from the Nebo Hill region around Kansas City, Missouri) was found along with an occasional wooden tool. Subsequent habitations include Middle and Late Woodland encampments that generally have larger-sized storage pits containing the same suite of plant foods as for the Sedalia phase; one well-defined oval house and a distinctively local, hematite-tempered ceramic are present.

The Phillips Spring site is now beneath the waters of Harry S. Truman Lake, a federal impoundment.

Phon, Kaseka

Kaseka Phon
Archaeology Department, Institute of Culture and Fine Arts, Royal Academy of Cambodia, Phnom Penh, Cambodia

Basic Biographical Information

Kaseka Phon graduated from the Faculty of Archaeology, Royal University of Fine Arts in Phnom Penh, Cambodia, in 2000. He is currently Director of the Archaeology Department at the Royal Academy of Cambodia, as well as a Ph.D. candidate at the same institution.

Major Accomplishments

He has extensive archaeological research experience across Cambodia. His research on the Cheung Ek archaeological site began in 2002. In 2002 he worked on "The East Cambodia Archaeological Survey" organized by the NAGA Research Group. In 2003–2004, he worked at the site of Phnom Borei, Takeo province, exploring its relationship with the nearby site of Angkor Borei. In 2004–2005, he began site survey and mapping at Cheung Ek with support from the NAGA Research Group. In 2005–2006, he worked on a site-mapping project in Ang Snoul district. Fieldwork at Cheung Ek continued in 2007 with a project of archaeological investigation and CRM supported financially by the US Embassy. In 2007, he conducted survey and mapping in Baray district, Kampong Thom province, as well as directing the Sre Ampil Archaeological and Conservation Project supported by the Center for Khmer Studies (CKS). In 2008, this project was expanded into a theoretical and practical training workshop in order to develop a coherent research and teaching program in the field of archaeology at the site of Sre Ampil. The CKS Junior Faculty Training Program (JFTP) as well as the Scaler Foundation and the Rockefeller Foundation jointly funded the project. In 2009, he trained site guardians at Prasat Banteay Chmar in a project funded by the Friends of Khmer Culture. That same year, he participated in the Industries of Angkor Project (INDAP), directed by Dr. Mitch Hendrickson at Preah Khan of Kompong Svay, Preah Vihear province. In 2011 and 2012, Kaseka Phon directed two projects supported by the Royal Academy of Cambodia. The first involved site survey and mapping in Trapeang Prasat district, Udor Mean Chey province. The second project involved survey and mapping of Buddhist Vihara Mounds at Udong and Lovek Cities. Most recently, he has returned to do fieldwork at the site of Cheung Ek, examining ceramics kilns and temple foundations in this area, as well as creating a ceramic typology. To date (August 2012), 61 pottery kilns and 11 temple foundations have been recorded. The survey and upcoming excavation is supported by the Friends of Khmer Culture. He also has been involved in many translation projects including *Early Cultures of Mainland Southeast Asia* by Dr. Charles Higham (funded by the Luce Foundation), a guidebook entitled *Guidelines for Stone Conservation and Preservation in Angkor* (funded by German Apsara Conservation Project) and *Archaeometallurgy* (funded by the Center for Khmer Studies).

Phytolith Analysis on Soil and Ceramic Thin Sections

Luc Vrydaghs[1,2,3] and Yannick Devos[3]
[1]CreA–Patrimoine ULB, Free University of Brussels, Brussels, Belgium
[2]Research Team in Archaeo- and Palaeo- Sciences (ROOTS), Brussels, Belgium
[3]Centre de Recherches en Archéologie et Patrimoine, Université Libre de Bruxelles, Brussels, Belgium

Introduction

Opal phytoliths basically make up a kind of puzzle of inorganic bodies accumulating within different plant organs (such as leaves, inflorescence bracts, fruits, and seeds) and tissues (such as the epidermis, the vascular, or the parenchymatic tissues) of many plants. Such a puzzle is often composed of many different shapes or morphotypes, a phenomenon called multiplicity (Rovner 1971). Similar morphotypes can also occur within related and unrelated plant taxa, a phenomenon called redundancy (Rovner 1971). Therefore opal phytolith analysis and their botanical identification are a complex matter. As they accumulate within plant tissues and organs, any opal phytolith signature in soils and sediments implies depositional processes that include the decomposition of organic matter. In the past, it has been assumed this decomposition occurs in situ and as such captures a signature of the local vegetation.

In relation to the botanical identification of phytoliths, the potential of morphometry, the measurement of sizes and shapes, was explored to deal with the multiplicity and redundancy issues. While collecting reference data does not compose a major problem for such studies, applying these data to archaeological material appears more problematic. Without considering the fact that a statistically valid set of measurements needs to be achieved, one needs also to be sure that all the measured phytoliths not only derive from the same plant but also from the same plant organ. Only some specific contexts such as the content of former jars (see, e.g., Berlin et al. 2003) provide such secure sources of phytoliths.

Traditionally, phytolith studies of soils and archaeological deposits involve the taking of bulk samples and placing the material into plastic bags. In the laboratory, the samples are put into various solutions and vigorously stirred to extract the phytoliths. As a consequence, the original distribution (e.g., the puzzle-like structure) of the phytoliths within the soil or sediment is lost ending up in a systematic mixing of phytoliths deriving potentially from different plant organs of different specimen of several plant taxa. This approach thus presumes that all phytoliths within a sample share the same depositional history. In archaeological contexts this is not necessarily the case. Consequently, besides mixing phytoliths with different botanical origin, the classical methods for phytolith analysis also potentially mix phytoliths with different depositional histories, thus creating an artificial signature which amplifies the multiplicity and redundancy issues. This is at the origin of several problematic issues (for a review of some of these issues, see Shillito 2013 and Vrydaghs et al. 2016). Integrating phytolith analysis with micromorphology, the study of sediments and soils in thin sections, composes a useful alternative to the more destructive and disruptive extraction methods commonly used for the analysis of phytoliths in soil and sediments (Vrydaghs et al. 2016).

Definition

Phytolith analysis on soil thin sections is a technique that inventories the distribution patterns of the phytoliths within soils and sediments as well as the phytoliths composing each of these distribution patterns. This allows a better understanding of the origin and depositional history

of the phytoliths. In contrast with classical phytolith studies performed on bulk samples, thin sections preserve the relative distribution of the phytoliths and their relation to other components. By documenting such relationships, classical but still problematic phytolith issues can be addressed, the major ones being their taphonomy and botanical identification.

Historical Background

Phytoliths are frequently reported within soil thin sections of archaeological deposits, being it cave or open-air contexts, from prehistoric to recent periods (Vrydaghs et al. 2017b).

Bullock et al. (1985) present phytoliths as part of the inorganic residues of biological origin. Stoops (2003) is the first to elaborate on a two-dimensional analytical and descriptive system of phytoliths within soil thin sections. It considers shape (angular versus rounded) and surface roughness. As such, this system is relevant for performing morphotypological analysis. He also recommends to note the distribution of the phytoliths while specifying they appear mainly in groundmass and infillings (Stoops 2003: 73–74).

More recently, several studies associating phytolith analysis and micromorphology were conducted (Shahack-Gross et al. 2005; Albert et al. 2008; Barczi et al. 2009; Madella and Lancelotti 2012; Shillito and Ryan 2013; Polo-Díaz et al. 2016). Most of these contributions can be ranged under two broad categories:

- Documenting the presence of phytoliths within archaeological units
- Documenting the phytolith distribution within archaeological units

These studies typically do not attempt to identify or quantify the phytoliths observed in the thin sections.

Since 2000, the phytolith analysis of soil thin sections is part of the routine analysis of urban Dark Earth units in Brussels (Belgium) (Devos et al. 2011). These Dark Earths are thick, dark-colored, homogeneous deposits covering large surfaces often encountered in urban contexts (Nicosia and Devos this volume). The purpose of these analyses is to present a comprehensive account of the phytoliths and their distribution patterns recorded during the scanning of the soil thin sections. Such an approach does not only allow the morphological identification of the opal phytoliths composing the distribution patterns but also to decipher their distribution within the archaeological units. As such, it informs about the processes leading to their incorporation within archaeological deposits. The results underline the potential of phytolith analysis on soil thin sections of archaeological deposits to identify the processes behind the formation of archaeological processes and the identification of several activity areas.

While the observation of opal of biological origin within petrographic thin sections is not uncommon, the systematic examination of phytoliths in ceramic thin sections is rare (Delhon 2005–2006) and presently restricted to a few case studies. To date besides an extensive study of material from the Arabian Gulf (site of Ed-Dur, Umm al-Quwain, UAE) (De Paepe et al. 2003; Vrydaghs et al. 2014), phytoliths have been recorded within thin sections of ceramics from Europe and Central Africa.

Key Issues/Current Debates

A first key issue concerns the taphonomical history of the phytoliths within archaeological deposits. In archaeological research, opal phytoliths are traditionally viewed as indicators of on-site plant use. The basic paradigm of the phytolith taphonomy states that they tend to be released through "decay in place" mechanisms. However, in archaeological contexts, a great variety of agents such as fire (Madella 2003), dung deposition and/or decomposition (Shahack-Gross 2011), and plant processing (Harvey and Fuller 2005) can be at the origin of phytolith deposition. In case the decay takes place after the burial of the plant fragment, the relative distribution phytoliths had within the plant tissues should be preserved

provided the soil or sediment has not been affected by post-burial perturbations. Following their incorporation into the sediment, fossil diagenesis (sensu Madella and Lancelotti 2012) can occur leading to specific (combinations of) distribution patterns within the sediments. The reconstruction of the depositional history as well as the fossil diagenesis of the phytoliths composes a major contribution of the study of phytoliths in soil thin sections.

In order to gain robust phytolith data from the analysis of soil thin sections, the micromorphological study needs to be conducted first. This allows to better understand the taphonomical history of the elements, including phytoliths. Once the taphonomical history is evaluated and described, the phytolith analysis of the soil thin sections can be conducted. The data are obtained through the scanning of zones selected by the micromorphologist. It consists of a three-step approach, namely:

1. A systematic recording of each distribution pattern
2. The subsequent inventory of the phytoliths from each distribution pattern
3. The counting of each phytolith type from each distribution pattern to gain semi-numerical data

So far, three basic distribution patterns of opal phytoliths have been recorded within soil thin sections of archaeological units: isolated, clusters, and articulated.

– Isolated phytoliths are totally disarticulated and widely separated phytoliths (Fig. 1). As their origin cannot be confirmed, they could be viewed as regional paleoenvironmental markers.
– A phytolith cluster consists of a group of disarticulated phytoliths wherein not all phytoliths are necessarily of the same type or share the same orientation (Fig. 2). The clusters are understood as the typical markers of postdepositional perturbations, the physical reworking of the archaeological units being a typical illustration of it.

Phytolith Analysis on Soil and Ceramic Thin Sections, Fig. 1 Microphotograph showing an isolated trilobate phytolith (plain polarized light, site of Grote Markt, Lier, Belgium)

Phytolith Analysis on Soil and Ceramic Thin Sections, Fig. 2 Microphotograph showing a cluster of different morphotypes (plain polarized light, site of Petite Rue des Bouchers, Brussels, Belgium)

– The articulated phytoliths are those that appear to have maintained the relative distribution they had within the plant tissues in which they were produced (Fig. 3). Because this original distribution is largely preserved, scholars have confidence that all these phytoliths share a common botanical origin but also that the plant material was buried and then decayed in situ with no or minimal post-decay disturbance.

The phytolith analysis and description of a single archaeological deposit can record a combination of several patterns with varying

Phytolith Analysis on Soil and Ceramic Thin Sections, Fig. 3 Microphotograph showing an articulated system composed of different morphotypes (plain polarized light, site of Petite Rue des Bouchers, Brussels, Belgium)

frequencies. The combination (or absence of combination) of patterns provides significant criteria to discriminate archaeological layers. Additionally, according to the considered units, the varying frequencies of each pattern provide additional information to discriminate the different units of an archaeological site. These are consequences of the distribution of the phytoliths within the plant tissues and the deposition and decomposition processes of the botanical material as well as post-decay events.

As phytoliths are plant microfossils, their study allows to gather data on past plant communities (for illustration see Piperno 2006). Hence emerges the second key issue: the contribution of phytolith analysis of soil thin sections to archaeoenvironmental and/or archaeobotanical studies. As any phytolith signature is potentially a mixture resulting from human and natural processes, the processes responsible for their incorporation into the archaeological deposits should be identified. Taking into consideration the distribution patterns and their meaning allows to discriminate these processes and, subsequently, to identify a relevant and secure source of data according to the addressed research topic. One of the issues related to the reconstitution of the vegetation relates to the minimal phytolith count size for statistical confidence. Specialists traditionally count between 200 and 400 phytoliths within bulk samples. Recently, for archaeological purposes, a count size of 250 phytoliths was recommended (Zurro et al. 2016). In case of rare but significant phytoliths, this counting must be complemented by a scanning at magnification ×250. Available semi-numerical data point that comparable count sizes of isolated phytoliths can also be achieved by the analysis of soil thin sections (Vrydaghs et al. 2017). This has the advantage, in contrast to the study of the bulk samples, that the depositional history can be taken into account.

Articulated phytoliths in soil thin sections are mainly observed as contiguous or silica skeletons. Regarding the latter ones and again according to the research topics, traditional phytolith analysis advocates the counting of 1 to 200 of them, without clarifying if this means a total of 1 to 200 silica skeletons or a sum of 1 to 200 individual phytoliths being interlocked. The only clear precision comes from research concerned by the search for evidence of agricultural practices involving irrigation. In such cases 300 articulated phytoliths are recommended (Rosen and Weiner 1994).

Morphometric analysis of articulated systems can provide adequate data for the botanical identification with greater reliability than the analysis of isolated phytolith assemblages. Indeed, with articulated phytoliths scholars are confident these phytoliths share a common botanical origin. Typically when trying to discriminate between phytolith assemblages produced by closely related taxa, one must rely on significant differences in the mean morphometries of the taxa. The latter are only reliable if they are calculated from an adequately large sample size. Previous calculated minimal count size for the morphometrical analysis of archaeological phytoliths equals 50 with 4 types of phytoliths being measured, implying that the morphometrical analysis of archaeological material relies on a total of 200 phytoliths (Berlin et al. 2003). For the dendritics, it has been established that with eight articulated phytoliths, the minimum adequate sample size requirements for the morphometry being used to discriminate among the cultivated taxa is already reached (Ball et al. 2017). Compared to previous

approaches, it does not only rely on a consistently smaller adequate sample size but also considers one single type of phytoliths. Integrating phytolith analysis with micromorphology has thus the potential to broaden the perspectives for morphometrical analysis of archaeological phytoliths, provided that reference collections are developed accordingly. Such an effort is currently undertaken for the phytolith deriving from the inflorescence of cereals, the so-called dendritics (Ball et al. 2017).

A third issue concerns the development of the study of phytoliths within ceramic thin sections. Pioneering phytolith studies establish that phytoliths observed within the mineral fabric help refining the source of clay identified by the petrographic analysis. As for those occurring within the voids, experiments indicate they derive from the plant material used as temper (Petö and Vrydaghs 2016). And as the occurrence of phytoliths within voids results from the oxidation of plant material used as temper, it can be assessed that all the phytoliths within a single void share a common botanical origin. This provides an additional source for botanical identification of opal phytoliths. Therefore, specific attention needs to be payed to the distribution of the opal phytoliths, namely, within the mineral fabric or the voids.

International Perspectives

So far, the application of phytolith analysis of soil thin sections from archaeological deposits as described within this entry primarily focuses on the study of Roman and Medieval urban Dark Earth from Northwestern Europe with a major emphasis on contexts from Belgium and Northern France. Recent studies performed on soil thin sections from Çatal Höyük (Shillito 2016) show that these studies can also be applied in older urban contexts.

As for the ceramics, phytolith analysis of soil thin sections have been performed on materials from different periods, originating from different continents (Africa, Asia, and Europe).

Future Directions

Attendance to various international workshops on the micromorphology of archaeological deposits highlights the record of opal phytoliths within soil and sediments thin sections is not restricted to the ones of urban contexts. Thin sections from other contexts with various geographical origins for different time periods, ranging from prehistory to modern times, are also characterized by a phytolith content. This is not surprising considering the huge occurrence of phytoliths within archaeological contexts. So if phytolith analysis of urban contexts, typically having a complex formation history, could be achieved by the means of the analysis of soil thin sections, it implies that it could also be accomplished for other archaeological units with less complex formation processes where the mixing of the material is less marked if not absent. This could consistently enlarge and enrich the contribution of opal phytoliths to archaeological research not only by deciphering their depositional histories but also through their botanical identification.

As ceramics are among the most frequent remains unearthed during excavations, expending the phytolith analyses of petrographic thin sections composes certainly another very large field of investigations. It suggests also that phytolith analysis could be expanded to the study of most of other earthen-based building materials (e.g., beaten floors, daub, and bricks).

Phytolith Studies in Archaeology

Philippa Ryan
Department of Conservation and Scientific Research, The British Museum, Great Russell Street, London, UK

Introduction

Phytolith analysis is a micro-botanical technique used in archaeology to study ancient plant remains. Phytoliths are opaline silica bodies formed during the lifetime of a wide variety of plant taxa within and between certain cells. These micro-remains can provide insight into ancient diet, the non-food uses of plants (such as for fuel or weaving), spatial arrangements of plant use and discard across settlements, agricultural practices, and seasonality of pre-agrarian site occupations. The durability of these micro-remains makes them particularly valuable at archaeological sites where preservation conditions are not suited to the survival of charred, desiccated, or waterlogged macro-remains. Phytoliths provide both complementary and unique information about plant use at sites where charred macrobotanical remains (cereals, seeds) are present since these datasets preserve information about different suites of plant parts and enter the archaeological record through different taphonomic routes. Outside the field of archaeology, phytoliths from soils and sediments are frequently used to reconstruct vegetation and climate histories.

Definition

The term phytolith derives from the Greek for plant "phyton" and stone "lithos." The term phytolith is most commonly used to discuss silica particles within plants, especially within archaeological studies, but does also refer to other types of mineral deposits. Only silica particles are discussed here. Phytoliths are formed when monosilicic acid (H_4SiO_4), present within groundwater, is taken up by various plant families and deposited as opaline silica within or between certain plant cells. Phytoliths are generally silt sized and have a refractive index of 1.41–1.47 and a specific gravity between 1.5 and 2.3. These microfossils are formed in different plant parts, depending on the taxa, and most commonly within epidermal cells of aerial structures (such as leaves, stems, seed bracts, and fruit rinds) but also sometimes within wood, mesophyll, and roots. Silica deposition can be both actively controlled by plants through physiological and genetic mechanisms and in relation to specific cells and passive potentially leading to silicification of a more variable range of cells and areas of plant tissue. For example, the production of grass "short cells" (rondels, saddles, bilobes, and crosses) is considered to be genetically controlled (Fig. 1), but levels of phytolith production and the range of silicified cells can be enhanced by environmental conditions that influence water uptake and soluble silica levels in groundwater (Mithen et al. 2008; Madella et al. 2009). Areas of epidermal tissue can become silicified, and these conjoined phytoliths are commonly referred to as silica skeletons (Fig. 1) (Rosen 1992). Sometimes, silica skeletons can be macroscopically visible; at Çatalhöyük, evidence for

Phytolith Studies in Archaeology,

basketry and brick temper survives as whitish traces of whole plant parts (Ryan 2011).

Historical Background

Phytolith research emerged in the early nineteenth century, and there are several distinct periods of phytolith research (Piperno 2006). In the 1830s, Christian Gottfried Ehrenberg coined the term "phytolitharia" and famously recognized these fossilized plant cells in dust samples collected by Darwin on the HMS Beagle voyage. From the end of the nineteenth century through to the mid-1930s, a phase of botanical studies was centered around Germany, and also during this time frame, cereal phytoliths were first recognized at archaeological sites. A broader range of botanical and ecological studies, including paleobotanical research, began from the 1950s, and in 1971, Irwin Rovner published a key article about the use of phytoliths in paleobotanical studies (Rovner 1971). From the end of the 1970s, large-scale research projects began to investigate vegetation histories and prehistoric plant use in the New World lowland tropical forest, as well as elsewhere in the Americas (Piperno 2009). Dolores Piperno (1988) published the first major book dedicated to phytolith research. Numbers of phytolith studies increased substantially during the 1990s and dramatically from 2000 onward.

Key Issues/Current Debates

Research questions addressed with phytolith analysis include the study of ancient diet, plant domestication, crop processing, non-dietary uses such as for fuel, spatial arrangements of plant use at archaeological sites, and the identification of ancient field systems. There are interpretative considerations specific to different geographic regions, for instance, concerning the degree of taxonomic information that relevant taxa can provide. Different site types, such as caves, shell middens, and urban settlements, also necessitate particular approaches. Ongoing investigation to establish phytolith identification criteria and to understand taphonomic factors remains important fields of research for phytolith studies both within and outside of archaeology.

Taphonomic Considerations

There are many factors to be considered when interpreting the phytolith record, including phytolith formation within plants, the cultural pathways

of plants into the archaeological record, and post-depositional factors. A recent review of pre- and postdepositional processes can be found in Madella and Lancelotti (2012). Phytoliths are released into soils when plants decay or are burnt, and for the most part, those in archaeological sediments will act as good indicators of on-site plant use (Piperno 2006: 105). In general, phytoliths are not transported over long distances with some exceptions, such as dust or sandstorms. The potential impact of factors such as soil formation and bioturbation may vary by region and site type. Although very robust, phytoliths can be destroyed in very alkaline soils (above pH 9). The shape and chemical properties of individual phytoliths can variably impact rates of dissolution (Piperno 2006: 108, 123). Phytoliths can also be mechanically damaged, for instance, through trampling or sweeping in antiquity. Different laboratory processing methods will also affect numbers of conjoined cells in silica skeletons (Jenkins 2009).

Sampling and Archaeological Questions

Sampling strategies will vary depending upon site type, for instance, between tell sites, shell middens, or caves. Samples should be taken, when possible, from tightly defined features likely to contain concentrated plant remains, such as storage areas, hearths, and ash lenses, as phytolith data may then reveal information about the specialized functions of certain areas (Piperno 2006: 83). In sites (or areas of sites) where no clear features are apparent, samples can be taken at regular intervals across surfaces or vertically between site levels. Control samples from sterile layers or off-site sediments are also important. Most samples are taken in the field, but samples of micro-lenses can also be taken from micromorphological blocks in the laboratory (Madella and Lancelotti 2012).

Sediment samples taken for phytolith analysis can be taken at two scales of analysis: at the scale of the excavation unit defined by site excavators and from smaller "spot" samples within these units. These "small-scale contexts" can be used to examine microdistribution patterns (Rovner 2001). Spot samples can be taken across horizontal surfaces, for example, across floors within buildings. Spot samples can also be taken vertically from micro-lenses within sections, for instance, through floors or rubbish deposits to investigate specific depositional events. Alternatively, for contexts such as rubbish deposits, subsamples from bulk sediments (at the scale of the excavation unit) may be useful for analyzing temporal and spatial trends by enabling a greater number of archaeological contexts to be studied. Such bulk samples are also directly comparable with macrobotanical or faunal datasets in terms of scale. If macroscopically visible silica skeletons are present, these are best sampled with a scalpel and placed in a small glass vial, as the individual signature of the plant will be lost if the silica skeleton disintegrates into surrounding sediments (Ryan 2011). Phytolith samples can also be taken from objects such as grinding stones (Radomski and Neumann 2011) or dental calculus (Henry and Piperno 2008).

Processing and Analysis

Phytoliths are typically extracted from sediments and soils through a series of laboratory steps. Usually around 0.5–2 g of sediment is processed, depending upon phytolith densities within sediments. Processing methods vary between researchers (Albert and Weiner 2001; Rosen 2005; Piperno 2006: 90–92), for instance, organics can be removed through chemical digestion or through ashing in a muffle furnace at 500 °C. Other processing steps include carbonate removal using a 10% solution of hydrochloric acid, clay removal through a settling process and the use of a 5% solution of sodium hexametaphosphate (Calgon) as a clay deflocculant, and a flotation stage using a heavy-density liquid such as sodium polytungstate made to a specific gravity of around 2.35 g/cm ^{3}. Phytoliths can be mounted onto slides using a suitable permanent fixative such as Entallin. Alternatively a liquid mounting medium like immersion oil is useful for studying the three dimensionalities of phytolith forms. Slides are scanned and counted using a light-transmitting microscope at around × 400 magnification. The amount of forms counted by researchers varies but commonly falls within

200–400 phytoliths and partly depends upon the frequency of rare types. Absolute counts (which are a measure of phytolith density) can be calculated per gram of sediment or (depending on processing methods) to the sediment's acid-insoluble fraction (AIF) (Albert and Weiner 2001; Rosen 2005). Relative abundances (percentages) among phytolith categories can also be calculated. There are advantages and biases inherent in using both absolute counts and relative abundances. Relative abundances (%) are useful for comparing phytolith assemblages from varying context categories with different types of sediments but can be problematic when a plant produces extremely large quantities of phytoliths as the variability among other lower phytolith-producing taxa among samples may be obscured. Phytolith images can be taken using a camera attached to a light-transmitting microscope, a scanning electron microscope (SEM) to examine three-dimensional form, or a variable pressure scanning electron microscope (VP-SEM) which enables imaging of cell wall patterning and phytoliths in their anatomical location (Ryan et al. 2012).

Several classification schemes exist for phytolith description. The International Code for Phytolith Nomenclature 1.0 (Madella et al. 2005) aims to create an internationally accepted protocol to describe and name individual phytoliths. Silica skeletons can consist of many types of plant cells arranged in their original anatomical location, and studies by grass systemists such as Metcalfe (1960) can aid identifications.

Key Phytolith Types

Phytoliths provide varying levels of taxonomic information. Some morphologies can be identified to family, subfamily, genus, and more occasionally to species. The greatest quantities and categories of taxonomically identifiable phytoliths are produced by monocotyledonous plants, especially grasses (Poaceae) and also by palms (Arecaceae), sedges (Cyperaceae), and the banana family (Musaceae). Phytoliths are also formed within many dicotyledonous woody tree and shrub plant families. Piperno (2006) provides an extensive review of phytoliths produced by different plant groups.

Grasses produce multiple phytolith forms providing varying levels of taxonomic information. Several important cereals (discussed below) and wild grasses produce diagnostic morphologies identifiable to genus level and more occasionally species. These diagnostic forms are most frequently from grass husks (seed bracts), but sometimes phytoliths from other plant parts are identifiable to genus level, for instance, *Phragmites* sp. (common reed) has recognizable leaf and stem multicell phytoliths (Fig. 2). With notable exceptions, less diagnostic cell types include various types of long cells, hairs, stomata, and bulliforms. Some phytoliths provide anatomical information, for instance, most commonly bulliform cells are associated with leaves and dendritic long cells with husks.

Grass "short cells" can broadly distinguish among several major grass subfamilies (Twiss 1992). The basic groupings are rondel forms (most common in the Pooideae, which includes wheat and barley), bilobe and cross forms (most common in the Panicoideae), and saddle-shaped forms (mostly found within the Chloridoideae subfamily). Pooid grasses have C3 photosynthetic pathways and are common in temperate climates and high altitudes, and chloridoid grasses and most panicoid grasses usually have C4

Phytolith Studies in Archaeology, Fig. 2 Multicell phytolith from *Phragmites australis* (common reed) leaf, showing saddle (**a**) and stomata (**b**) phytoliths; scale bar, 100 μm. (Image: PL Ryan; copyright Trustees of the British Museum)

photosynthetic pathways and are common in hotter environments, while chloridoid grasses are usually associated with aridity. There are exceptions; for instance, the saddle-producing chloridoid grass *Aeluropus* spp. grows in wetland habitats spanning arid to temperate climates. Also, some short cell types are present within more than one subfamily, for instance, in the Arundinoideae subfamily rondels and "saddle-topped short trapezoids" are found within *Phragmites australis* (common reed) (Fig. 2) (Ollendorf et al. 1988).

Phytoliths are also abundantly produced by sedges (wetland plants that superficially resemble grasses: family Cyperaceae). The most distinctive "cones" often derive from achenes and achene bracts, while less potentially distinguishing cone forms are also produced in leaf/stem areas (particularly leaves), as well as sometimes other cell types including stomata, hairs, bulliforms, and various types of long cells (Figs. 3 and 4). Phytoliths are also abundant in palms. Genus-level identification is problematic but depends on the range of regional palm genera. In the Near East, "spherical echinate" forms from date palms (*Phoenix dactylifera*) (Fig. 5) can be potentially distinguished from doum palm (*Hyphaene thebaica*) phytoliths that are generally larger and fall into two size groups (Rosen 1992).

Phytolith Studies in Archaeology, Fig. 3 Multicell phytolith from *Carex divisa* inflorescence bracts (sedge); scale bar, 100 μm. (Image: PL Ryan; copyright Trustees of the British Museum)

"Polyhedral," "jigsaw," and hair phytoliths (Fig. 6) are formed in certain dicotyledonous tree or shrub leaves (Bozarth 1992). Phytoliths can also be present within wood and bark, although up to 20 times lower than grasses and absent in some taxa (Albert and Weiner 2001). Silica deposits can be present in parenchyma, in axial parenchyma cells, in fibers, and in vessels (Metcalfe and Chalk 1983: 93). Phytoliths in bark may be secondarily deposited (for instance, from leaves). Phytoliths from woody plants are generally of irregular morphology (Albert and Weiner 2001). Phytolith forms can also derive from outer layers of certain dicotyledonous seeds and nuts, including *Celtis* sp. (hackberry).

Selected Phytolith Studies by Region and Crop Type

Many cereals and other crops have taxonomically diagnostic phytoliths that can be used to investigate plant diet and agriculture. Crop taxa have often been most intensively studied in regions where they were originally domesticated and where preservation of plant macro-remains has been poor – for instance, in lowland tropical areas or at pre-agrarian Epipalaeolithic sites in the Levant.

Phytoliths have been used to study wheat (*Triticum* spp.) and barley (*Hordeum* spp.) agriculture particularly in the Near East, where they were domesticated, and now increasingly in other areas including parts of Europe, Central Asia, and North Africa. The analysis of silica skeletons from Near Eastern cereal crops was pioneered by Arlene Rosen (1992), who outlined several criteria for identifying husks from wheat (Fig. 7), barley, and three wild grasses from the Pooideae subfamily: oat grass (*Avena* spp.), rye grass (*Lolium* spp.), and goat grass (*Aegilops* spp.). Identification criteria are yet to be defined for husk silica skeletons from many Pooideae grasses but can sometimes still be identified as "wild grass husk" (Fig. 8). Key identifying features include the undulating wave patterning created particularly by the dendritic cell walls and the shape and ornamentation of papillae cells (Fig. 7). Individual papillae cells can differentiate between wheat and barley at genus level as well as among

certain species (Tubb et al. 1993). Ball et al. (1999) used computer-based scanning software to study the morphometrics of individual husk cells from several wheat and barley species and, from this, developed a classification key as well as discriminant function tests that were able to distinguish among these taxa (confidently to genera and often to species depending on the method). Morphometric analysis of single cells can be applied to sample contexts where phytolith assemblages are likely to contain husks from cereals rather than a wide range of grasses, as other Pooideae grasses may have overlapping cell measurements (Ball et al. 1999).

Archaeological applications of phytoliths in the Near East have been increasingly applied across a wide range of periods and settlement types. For instance, phytoliths have been used to study pre-agrarian shifts toward wild grass exploitation at late Natufian Levantine settlements (Rosen 2010), early agriculture and plant use at Neolithic sites such as Çatalhöyük (Rosen 2005; Ryan 2013), and urban centers such as Bronze Age Tel Dor (Albert et al. 2008). Studies from cave sites including from Middle Paleolithic through to Natufian levels have revealed information about plants used for fuel (Albert and Weiner 2001) as well as about possible Neanderthal wild grass husk exploitation (Madella et al. 2002). Other studies have investigated wheat and barley phytoliths as indicators of crop-growing conditions. A pioneering study by Rosen and Weiner (1994) showed numbers of conjoined cells in

Phytolith Studies in Archaeology, Fig. 7 Silica skeleton from *Triticum durum* husk (durum wheat), including dendritic (**a**) and papillae (**b**) phytoliths; scale bar, 100 μm. (Image: PL Ryan; copyright Trustees of the British Museum)

Phytolith Studies in Archaeology, Fig. 8 Silica skeleton from *Bromus* sp. husk (bromegrass); scale bar, 100 μm. (Image: PL Ryan; copyright Trustees of the British Museum)

cereal husk silica skeletons increased with irrigation. Madella et al. (2009) have shown the ratio of short cells and long cells from leaves, and stems can act as an indicator of water availability, while Jenkins et al. (2011) have outlined a further method using the ratio of short cells to dendritic long cells from cereal husks.

New World crop phytoliths, especially maize (*Zea mays*), have a long history of research. Large-scale modern reference studies led by Dolores Piperno and Deborah Pearsall since the late 1970s and centered around the lowland Neotropics have enabled size and morphological criteria to be developed to identify particular cross-shaped phytoliths from maize leaves and to distinguish these from wild grass populations (see references in Piperno 2009). Studies from the subtropical panicoid grasslands of southern South America have shown the criteria hold elsewhere (Iriarte 2003). Distinctive phytoliths within maize cobs were recognized from the mid-1980s in studies by Susan Mulholland and Steven Bozarth in North America (for references see Piperno (2009)). Large-scale reference studies of cob and fruit-case phytoliths have been carried out; maize and its wild ancestor Balsas teosinte (*Zea parviglumis*) can be distinguished, with wavy top rondels diagnostic of maize cobs and ruffle top rondels identifiable at the *Zea* genus level (Pearsall et al. 2003; Piperno 2009). Other well-studied New World crop phytoliths include distinctive scalloped phytoliths from the fruit rind of the *Cucurbita* genus, first recognized by Steven Bozarth in the 1980s, which have been used to study the history of domestic squashes and gourds and sometimes to distinguish between wild and domesticated species (Piperno 2009). Archaeological applications have included investigations of sediments from prehistoric settlement sites and agricultural terraces, as well as of residues from grinding stones and other food-related artifacts including pottery (Piperno 2006, 2009).

The potential of rice phytoliths to investigate the origins of Asian rice agriculture is also well established. Large reference studies of rice and related wild grasses from southern China have been undertaken and phytolith identification criteria established (Pearsall et al. 1995; Zhao et al. 1998). The *Oryza* genera can be identified from double-peaked hair cells (from husks), and further characteristics have been suggested to differ between wild and domestic species, although these remain controversial (Fuller et al. 2010). Other cell types identifiable to the rice genus are keystone bulliforms with flared edges. These show differences between *indica* and *japonica* subspecies of rice, although this variation is also found in wild populations, making application of this useful in regions like Japan without wild rice (Zheng et al. 2003).

Millet phytoliths have seen comparatively less focus. Foxtail and common millet were staple foods across the Far East and also important across Eurasia. Modern phytolith reference studies have defined identification criteria for common millet (*Panicum miliaceum*) and foxtail millet (*Setaria italica*) based on several characteristics of husk silica skeletons including the undulated patterns of epidermal long cells (Lu et al. 2009). Similar criteria have also been developed to distinguish foxtail millet, the predominant Neolithic crop in northern China, from its wild ancestor green foxtail (*Setaria viridis*) (Zhang et al. 2011). The potential of phytoliths for identifying several other millet species is demonstrated by Madella et al. (2013). Harvey and Fuller (2005) investigated how crop-processing models can inform analysis of millet and rice phytoliths and applied their model to a Neolithic site in India.

There have been comparatively few phytolith studies of African crops and archaeological settlements. A recent study has examined inflorescence phytoliths from wild and domesticated West African grasses and applied this to the analysis of phytoliths from archaeological grinding stones in the Eastern Sahara and Western Sahel savannah (Radomski and Neumann 2011). Findings included that certain cross and bilobe phytoliths could be used to group some grasses within the Paniceae tribe and that *Digitaria* (which includes the crop fonio) was distinguishable due to papillae density, while sorghum husks had distinctive bilobes and dendritic long cells. Many Panicoideae grass genera are known, such as *Panicum* and *Sorghum*, to potentially produce husk silica skeletons (Fig. 9), and further identifications of African millet grasses may be possible with multicell identification methods analogous to those applied to common and foxtail millet (above). However, the applicability of this method will depend on the presence of silica skeletons in archaeological samples as opposed to predominantly single cells, which may vary in likelihood among genera and be influenced by plant-growing conditions such as water availability in very dry environments (as well as post-taphonomic factors). Madella et al. (2013) show the potential of husk long cell phytoliths (in single and multicell form) for identifying millet species, including *Sorghum bicolor* and *Pennisetum glaucum* (pearl millet). Phytoliths of bananas (*Musa* sp.) have been shown to differ from those of indigenous African *Ensete* (Vrydaghs et al. 2003). Archaeological applications of phytolith analysis in Africa span vastly contrasting landscapes, time frames, and settlement types, including early modern human plant exploitation from cave sites (Albert and Marean 2012), equatorial forest sites during the Late Stone Age (Mercader et al. 2000) to Late Holocene settlements such as a Numidian site in Tunisia (Portillo and Albert 2011), and the New Kingdom colonial town of Amara West in northern Sudan (Ryan et al. 2012).

Phytolith Studies in Archaeology, Fig. 9 Silica skeleton from *Sorghum bicolor* husk (sorghum), including sorghum-type bilobe (**a**) and dendritic-type phytoliths (**b**); scale bar, 100 μm. (Image: PL Ryan; copyright Trustees of the British Museum)

Patterns of Plant Use, Processing, and Disposal at Archaeological Sites

Phytolith categories found on archaeological sites can provide important information about agricultural practices, habitats exploited, wild plant foods, and non-dietary plant uses. Phytoliths from woody species, palms, grasses, and sedges may provide important information about plants burnt for fuel, while the presence of sedges and reed phytoliths provides information about

wetland exploitation. Phytoliths can potentially be used to study spatial arrangements of plant use and discard across archaeological settlements. Locations of plant use may be suggested through quantified "peaks" of certain phytoliths across surfaces or features studied. It is often possible to identify phytoliths from different plant parts, enabling investigation of crop-processing practices (Harvey and Fuller 2005), as well as the use of leaves and stems in basketry, building materials, and fuel. Distributions of cereal husk or straw phytoliths can be studied to investigate spatial arrangements of cereal storage, processing (such as dehusking), crop by-product disposal, as well as the secondary use of crop-processing by-products.

Different input sources can be explored by investigating a wide range of archaeological contexts and materials. Analysis of varied sample categories at Neolithic Çatalhöyük in Central Anatolia (including storage bins, ovens, fire spots, floors, mudbricks, basketry, and dung pellets) enabled detection of spatial patterns of plant use, processing, and disposal (Rosen 2005, Ryan 2013). Large quantities of plant materials were incorporated into raw materials such as mudbricks, including cereal chaff and wetland plants (Ryan 2011). Samples from storage bins provided information about storage, and locations of cereal dehusking were identified within buildings. Phytoliths from bulk sample analyses (from middens) spanning over 1000 years of site occupation enabled detection of long-term changes in plants present (Ryan 2013), while phytolith samples from micro-lenses from particular midden sequences provided perspectives on discrete episodes of plant deposition (Shillito 2011; Ryan 2013). Animal dung can be an important route for phytoliths into archaeological contexts, for instance, through stabling or the use of dung as fuel, and analysis of calcareous spherulites can be analyzed as a proxy for herbivore dung (Portillo and Albert 2011). At sites where dung pellets are present, phytoliths can be extracted from dissected pellets and may provide perspectives on foddering or grazing practices.

Regionally relevant ethnographic and ethnobotanical studies can provide useful analogies about certain plant uses, such as for food or fuel, and about their processing and disposal. Harvey and Fuller (2005) showed how crop-processing models (derived from ethnographic studies of traditional farming) could be applied to the analysis of millet and rice phytoliths, in terms of interpreting which phytoliths derive from by-products produced by specific processing stages, and this approach is also applicable to other cereals. Prior to storage, crop-processing stages include threshing, winnowing, and sieving. Some cereals, such as glume wheat, require an extra processing stage (potentially post storage) to remove husks. Different by-products created during each stage may potentially be collected for use as fuel or fodder or may become incorporated into other materials such as temper in dung cakes or in building materials. There have been a small number of ethnoarchaeological phytolith studies, such as Tsartsidou et al. (2008), which involve taking samples from present-day or recently abandoned settlements to investigate phytolith signatures from different types of site area or deposits.

Integrating Botanical Datasets

Charred macro-remains and phytoliths can provide unique and complementary data through offering information about different plant parts and by surviving through different taphonomic processes (Bates et al. 2017; Harvey and Fuller 2005; Ryan et al. 2016). Charred macro-remains can identify a wider range of taxa than phytoliths; however, phytoliths will provide information about plant parts that do not frequently survive charring, such as leaves and stems, and about plants present in ashy contexts where charred macros are entirely destroyed by high temperatures. Phytoliths may also provide separate categories of information about plant use in non-burnt site areas or materials. Some studies have also combined starch and phytolith results, especially in the case of samples taken from artifacts or dental calculus and also particularly in studies from the Americas (Henry and Piperno 2008; Madella et al. 2014; Piperno 2009). Starch will provide information about non-phytolith-producing plant parts, including cereal grains and tubers.

International Perspectives

Phytolith research is a worldwide discipline, with two major international conferences. The International Meeting on Phytolith Research (IMPR) is convened by the Society for Phytolith Research. The South American Meeting on Phytolith Research (Encuentros de Investigaciones FitolÃšticas (EIF)) is convened by the Grupo de Estudios FitolÃšticos Aplicados del Cono Sur (GEFACS).

Research trajectories can often be regional, especially when investigating early agriculture. However, many crops have wide geographic distributions in later time periods and are increasingly studied across different continents within phytolith research. Many non-dietary phytolith-producing plants also have wide geographic distributions (such as reeds) and thus relevance to researchers, especially when considering identifications at genus or plant family level. Discussions of approaches to studying phytoliths from certain types of archaeological sites can also have cross-regional relevance, while other research questions pertain to regionally specific cultural or environmental settings.

Future Directions

Certain regions and time periods are less well studied than others, with areas of major crop domestications having the most extensive history of research. There are a number of phytolith-producing crops that have so far seen little/emerging research, such as African cucurbits and various African, southern Indian, and southeast Asian millet grasses (Piperno 2006: 79). Ethnoarchaeological phytolith research projects in contemporary or abandoned settlements offer another new area of emerging research as so far there have only been a handful of research projects using this approach. Future directions could also include further integration between phytolith, charred seed, and charcoal datasets at archaeological sites to provide complimentary datasets from both the same sediment samples as well as comparing overall results. Comparing starch and phytolith results, especially from artifact residues, is a well-established technique in some regions such as the Neotropics (Piperno 2009) and less frequently applied in other areas such as the Near East.

Phytoliths in Archaeology: Chemical Aspects

Martin J. Hodson
Faculty of Health and Life Sciences, Oxford Brookes University, Oxford, UK

Introduction

Phytoliths have now become almost a routine aspect of many archaeological investigations. They are very widely used in many contexts to gain information about the plant species grown by or associated with humans in the past. Up until relatively recently most workers have used phytolith morphology to investigate archaeological contexts, and still the majority of papers published take that approach. However, there is increasing interest in using the chemical or even isotopic makeup of phytoliths to provide more information than is available merely from using morphology. The second key area where phytolith chemistry is important in archaeology is taphonomy. In particular, phytoliths with different chemistries might be expected to degrade in soils or sediments at different rates, and soil chemical conditions may also affect degradation. Both these factors could seriously impact on the interpretation of phytolith results from archaeological contexts.

Philippa Ryan wrote an excellent overall introduction to the use of phytoliths in archaeology for the *Encyclopedia of Global Archaeology* (Ryan 2014), but of necessity the coverage of the more chemical aspects of phytoliths and their potential for use in archaeology was brief. Although the number of archaeological investigations that have made direct use of phytolith chemistry is so far relatively small, the potential for the future is huge. Chemical aspects can also have potentially large effects on the taphonomy of phytoliths. In this entry I will outline the progress in these areas so far.

Definition

Ryan (2014) gave an overall definition of what phytoliths are in her paper and, like her, I will also only consider siliceous structures. From a purely chemical point of view phytoliths are deposits of amorphous silica that are formed within some plant cells. Other compounds and elements are often included in their structures, and these will be discussed below.

Historical Background

Phytoliths have been studied since the nineteenth century, but it is not easy to say when investigations of their chemistry began. However, it was undoubtedly Jones and Beavers (1963) who produced the first detailed chemical work. They carried out x-ray diffraction, infrared absorption, differential thermal analysis, specific gravity, and refractive index measurements on phytoliths. Another key figure in the early chemical work on phytoliths was François Bartoli whose work on crystallochemistry was seminal, and is still much cited (Bartoli 1985). In more recent times Carole Perry has been a leading figure in research into the chemistry of phytoliths (Currie and Perry 2007).

Key Issues/Current Debates

Phytoliths are found in leaves, flowers, seeds, stems, and roots in many different cell types. So, unlike the situation with pollen grains, a single plant species can produce many different morphological types of phytoliths. This has its challenges for phytolith analysts, but advances in image analysis and statistical techniques are steadily improving our ability to identify species from the mixture of phytolith types often found in archaeological

samples. It is less well recognized that because phytoliths form in different environments in the plant, they are not just morphologically different but chemically heterogeneous. Kumar et al. (2017) assessed the variation between different cell types in grass species. The main deposition sites observed were in the endodermis of the roots, the epidermis of the leaves, and the outer epidermis of the inflorescence bracts. Lesser amounts have been detected in other locations such as the brush hairs at the ends of some cereal grains. There are two main locations where silica deposition leads to formation of phytoliths: the cell wall and the cell lumen. The authors postulated three deposition mechanisms: passive cell wall silicification, controlled cell wall silicification, and deposition in silica cells where the phytolith develops on the external side of a functional plasma membrane. As phytoliths are formed in many different locations in the plant and the mechanisms of their formation are thought to vary, it should not be too surprising that their chemistries differ.

Silica

The silica deposited in phytoliths is amorphous with no order down to the level of 10 Å (Currie and Perry 2007; Hodson 2016b), and has the general formula $[SiO_{n/2}(OH)_{4-n}]_m$, where $n = 0$ to 4 and m is a large number. Occasional reports of crystalline material are probably either due to contamination or the silica being laid down on ordered cellulose molecules. The silica within cell walls is likely to differ markedly from that laid down in the lumen. Where silica is deposited in cell walls, it is laid down onto a carbohydrate matrix. When it is deposited in the cell lumen, the silica would not be expected to contain as much carbohydrate but might well contain the breakdown products of the protoplast: proteins, lipids, and nucleic acids among them. So the silica structure itself will vary depending on the matrix onto which it is laid down. The carbon within phytoliths has received much recent attention. The two other elements in phytoliths that have gained some interest are aluminum and nitrogen. Stable isotopes of silicon, oxygen, and carbon have all been suggested as potential proxies for use in archaeological work, and radiocarbon dating of phytoliths with ^{14}C has been widely used. All of these parameters could be useful in providing information beyond morphological analysis.

Carbon

Jones and Beavers (1963) were the first to measure carbon in phytoliths, estimating that those isolated from a Cisne silt loam had 0.86% C. They suggested that this carbon might be occluded within the phytolith and protected from oxidation (so-called phytolith occluded carbon). Since then there have been many attempts to measure carbon in phytoliths. Acid digestion, heating in a muffle furnace at 450 °C or more, and microwave digestion are the three most usual methods. The results vary depending on the methodology employed from 0.1% to 6.0% C or more (Hodson 2016b). Perhaps surprisingly, this has caused one of the major current controversies in phytolith research. For quite some time, researchers around the world have been interested in whether phytoliths might have the potential to sequester substantial amounts of carbon, and thus contribute to the fight against global warming. The percentage of carbon in phytoliths determined in laboratories using different techniques then has a major influence on the amount of carbon that is thought to be sequestered in soil phytoliths at an ecosystem or even a global scale. Song et al. (2017) consider that very low carbon concentrations are due to extreme preparatory techniques causing the disintegration of the phytoliths. Others have suggested that high carbon concentrations are unrealistic as much of the carbon measured will be labile, easily degraded in the soil, and therefore not strongly sequestered. My concern (Hodson 2016a) is that none of the methodologies used necessarily give good estimates of the carbon present in soil phytoliths. This topic might be considered tangential to archaeological concerns, but the carbon concentration of phytoliths in soils or sediments may be a factor in how quickly they degrade (see "Taphonomy" below).

What form does the carbon take in phytoliths? In cell wall phytoliths, such as those considered by Currie and Perry (2007), carbohydrates are

major components with smaller amounts of protein and amino acids. The type of carbohydrate present has a significant effect on the morphology of the silica produced. Rather less is known about lumen silica deposits, but it is likely that they are much lower in carbohydrates and potentially higher in lipids from the breakdown of membranes and possibly nucleic acids.

Other Elements in Phytoliths

Elements other than silicon, oxygen, and carbon have also frequently been found in phytoliths (Hodson 2016b), and there has been some interest in their use as potential markers in archaeological contexts, but so far I am unaware of any publications that have taken this idea forward.

Bartoli (1985) was among the first to work on aluminum in phytoliths. He found that phytoliths from conifers had a higher aluminum content than those from deciduous trees. Most of the aluminum seemed to be present on the surfaces of the phytoliths, and conifer phytoliths were significantly less soluble as a result. Unlike many other elements, it is possible for aluminum to substitute for silicon in the structure of a phytolith, isomorphous substitution. Carnelli et al. (2002) conducted a survey of 20 species growing in the Valaisan Swiss Alps. They confirmed that phytoliths isolated from woody taxa were higher in aluminum than those of monocotyledons and suggested that this could be used as a marker for woody taxa in paleoecological studies. However, aluminum concentration in phytoliths does not only depend on whether a species is woody but also whether the soil in which the parent plants are growing is acidic and has high available aluminum for uptake (Hodson 2016b).

Nitrogen was first reported in phytoliths at low concentrations by Jones and Beavers (1963). In wheat, Hodson et al. (2008) found between 0.01% and 0.06% N, depending on the organ that the phytoliths were isolated from. Findings like these suggest that amino acids, proteins, and nucleic acids could be among the nitrogenous compounds sequestered in phytoliths. Alexandre et al. (2015) used nanoSIMS to analyze individual wheat phytoliths and observed that both carbon and nitrogen appeared to be distributed throughout these structures and at an N/C ratio of 0.27. As the authors point out this suggests that amino acids are present. The one major attempt to isolate DNA from phytoliths was not successful, but glycoproteins were found (Elbaum et al. 2009). I suspect that as techniques for the detection of DNA get better and better there will be further attempts at isolating it from phytoliths. Success would revolutionize archaeobotany.

Stable Isotopes

There has been considerable interest in using stable isotopes in biogeochemical investigations and some work on isotopes in plant silica and phytoliths. The elements that have been investigated so far in phytoliths are silicon, oxygen, and carbon.

There are three stable isotopes of silicon, ^{28}Si, ^{29}Si, and ^{30}Si, with ^{28}Si being the most common in the environment. The ratios of these isotopes to each other are relatively constant but change when Si is deposited as a solid from a solution, a so-called fractionation event. In some situations the heavier isotopes come out of solution quicker leaving the solution with a greater proportion of lighter isotopes. However, it appears that in flow through situations the lighter isotopes come out of solution faster, leaving the heavier isotopes at greater concentrations in the solution (Hodson 2016b). So in wheat (Hodson et al. 2008), and all other plant species so far investigated, the heavier isotopes are concentrated higher up the shoot and further along the transpiration stream. This is an interesting and highly consistent observation that could eventually have uses in archaeology, as it suggests a method for distinguishing between stem and leaf phytoliths or stem and inflorescence phytoliths. As yet, however, there have been no such applications. Hodson et al. (2008) concluded "At present, then, we feel that the fractionation of heavy Si isotopes into the upper parts of plants is a finding that is awaiting an application." That remains the case.

There are three naturally occurring stable isotopes of oxygen, ^{16}O, ^{17}O, and ^{18}O, and the former is by far the most common in the environment. Because it is lighter, ^{16}O, when present in water molecules, is slightly more likely to evaporate than the heavier isotopes. This has led to many applications in geochemistry, and there

has been some interest in attempting to relate oxygen isotopes in phytoliths to the environments in which plants are growing (Hodson 2016b). However, there are many factors that influence evaporation of water from plants, and these tend to complicate the oxygen signal derived from actively transpiring tissues such as leaves. This led Alexandre et al. (2012) to investigate wood phytoliths in tropical forest trees in Queensland, Australia, that were growing along altitudinal gradients. These phytoliths should not be influenced by evaporation, and Alexandre et al. found that wood phytolith oxygen isotope signatures were related to mean annual soil water isotopic values and to mean annual temperature.

There are two stable isotopes of carbon, ^{12}C and ^{13}C, with the former being more common. These isotopes are important in paleoecology and archaeology as they can be used to distinguish between plants showing C3 and C4 photosynthesis. C3 plants generally prefer more mesic conditions, while C4 plants are better at surviving dry conditions. So the balance between C3 and C4 plants can give an indication of the aridity of the environment. Plants all discriminate against the ^{13}C isotope when it is taken up as carbon dioxide in photosynthesis, but C3 plants do so more than C4 plants. This means that C3 plants such as beans, rice, and wheat have markedly different isotopic signatures to C4 plants such as maize and sugar cane. This isotopic signal is then passed on to animals, including humans that have eaten either C3 or C4 plant products. Not surprisingly there has been some interest in measuring stable carbon isotopes in phytoliths. In general, this work has been successful and, for example, wheat phytoliths showed carbon isotopic signatures within the expected range for C3 plants (Hodson et al. 2008). However, there have been some problems with phytolith carbon signatures not matching those of the whole plant (Hodson 2016b), and this phenomenon has been even more pronounced with work on ^{14}C.

The Controversy Over ^{14}C

When they discovered that carbon was occluded within phytoliths, Jones and Beavers (1963) pointed out that it might be possible to use this in dating. Trace amounts of the radioactive isotope ^{14}C occur naturally in the environment with a half-life of 5700 years, and this is used routinely in dating of all types of materials. From the late 1960s onwards the technique was quite widely used on phytoliths and seemed to give good results. However, in recent years there have been a number of anomalous results reported where phytolith ^{14}C determinations were giving results that were hundreds or even thousands of years older than they were known to be (Piperno 2016). Phytoliths isolated from some modern plant material seem to give much older dates than the plants themselves. This finding has caused a great controversy, and sometimes a heated one, and as I write in 2017 there is still no definitive answer to the problem.

It is generally recognized that most of the carbon in phytoliths originates from photosynthetic carbon uptake. However, Santos et al. (2012) proposed that "old carbon" taken up by plant roots from the soil is transported through the plant and is incorporated into phytoliths, thereby making the phytoliths apparently older than the rest of the plant. They reviewed the evidence that a small amount of carbon is taken up by plants in this way and that it joins the much larger pool of photosynthetic carbon. My question concerning the "old carbon" hypothesis is the mechanism whereby transport of old carbon is focused towards the phytoliths. This would be required if they were to be apparently older than the plants from which they are derived (Hodson 2016b). I suggested that depletion of ^{14}C in lipids within phytoliths might be a possible explanation for the results.

Piperno (2016) analyzed phytoliths isolated from herbarium specimens of neotropical plants collected between 1964 and 2013. She found that the dates obtained were post-bomb ^{14}C dates, reflecting collection of the samples after 1955 after the beginning of thermonuclear testing. There was no suggestion of dates being older than expected, except for one sample which had originally been treated with organic chemicals made from fossil fuels that were radiocarbon dead. Piperno suspects that many of the problems arise from the methodologies used and that surface contamination with old carbon is a major difficulty.

The search for a reliable methodology was the focus of Asscher et al. (2017). They dissolved silica from phytoliths using mild conditions and released insoluble fractions which gave reliable radiocarbon dates. They compared their phytolith dating results with those for seeds from the same contexts at the archaeological site of Bet Shemesh in Israel. For insoluble material that was extracted from phytoliths where the percentage carbon was greater than 40%, the dating results were identical with the seeds. The authors also compared the percentage of modern carbon in phytoliths extracted from wheat plants (97.76%), from cellulose extracted from the plant (99.78%), and from the soil in which the plants were growing (72.53%). They suggested that the lowered modern carbon in the phytoliths was due to uptake of old carbon from the soil.

The importance of carbon dating of phytoliths is well illustrated by the work of Zuo et al. (2017). They used the technique to take the date of rice cultivation in China back to the beginning of the Holocene period between 9000 and 9400 cal year B.P., the earliest dates seen so far. The authors validated these dates by comparing them with other dated materials from the same level or context. The dates observed were apparently not affected by "old carbon." Zuo et al. concluded, "We find no evidence to support arguments from a few investigators that old carbon absorbed from soils bias phytolith dates."

Clearly, we have a major problem here with researchers split into those favoring the "old carbon" hypothesis, and those who think that the difficulties largely arise from methodology. Some look to fractionation events within the plant to explain the phenomenon, and yet others seem to be largely ignoring the issue. Carbon dating of phytoliths is a fundamental issue for many of their applications in archaeological science, and this disagreement needs resolution soon. It seems that the technical problems in obtaining clean samples have largely been overcome, but the problems arising from the "old carbon" hypothesis remain. Why do some researchers find carbon dating of phytoliths is unreliable, but others seem to find no problems? How does "old carbon" from the soil get concentrated into phytoliths? Are other processes within the plant responsible for the observed results? The answers to these questions require detailed investigations of the processes involved in phytolith formation.

Taphonomy

Phytoliths with a variety of chemistries are produced by plants, and these find their way into different archaeological contexts. Many are incorporated into the soil after the plant dies. Some plant parts will be harvested and either eaten or used in other ways. Phytoliths can be found associated with human or animal teeth. Sometimes the plant material will be burnt, leaving the phytoliths in the ash. In all of these situations the chemistry of the phytoliths involved will interact with the chemistry of the environment. In some cases the phytoliths will be highly resistant to dissolution and degradation, while in others they will soon disappear from the archaeological record. So the phytoliths remaining in a sample for morphological analysis will be affected to a considerable extent by chemistry.

Some soil conditions are known to increase the dissolution and breakdown of phytoliths, for example, high soil pH and temperature. Prentice and Webb (2016) investigated a pH range from 4.0 to 10.0, and temperatures between 4.0 °C and 44.0 °C and found that dissolution increased with higher pH and temperature. The authors also took this work a stage further by looking at changes in the isotopic composition of phytoliths during dissolution. In the early stages of dissolution the lighter isotopes ^{28}Si and ^{16}O were preferentially removed from the phytoliths leaving them enriched in heavier isotopes. However, once the surrounding solution reached 30–40% saturation, then precipitation of new silica onto the phytoliths began, and lighter isotopes were redeposited. This study suggests that changes in the isotopic composition of phytoliths after they are deposited in soils or sediments need to be taken into account, and that the complexities in using isotopes resulting from processes within the plant are exacerbated in the post-depositional environment.

Bartoli (1985) determined that aluminum deposited within phytoliths decreased their

solubility. As we noted above, conifer phytoliths are particularly high in aluminum provided that the trees producing them are growing in acidic soils with reasonably available aluminum. So we might expect that conifer phytoliths would dissolve more slowly than those from other species (e.g., grasses) and so might be overrepresented in the depositional environment.

Another factor that is likely to affect the solubility of phytoliths and how quickly they break down in soils or sediments is their organic matter content. When they are lost from the host plant, cell wall phytoliths will have a higher organic content (principally cellulose and other carbohydrates) than lumen phytoliths. I previously assessed the evidence that when this organic matter is lost from the phytolith, either through acid digestion, burning, or degradation in the soil, the remaining silica is fairly porous (Hodson 2016b). Thus, cell wall phytoliths may well be more susceptible to dissolution and breakdown within the soil. More work is undoubtedly needed in this area.

Osterrieth et al. (2009) investigated the taphonomical factors affecting phytoliths deposited in the loess sediments of the Argentinian Pampas. They considered that the moderately alkaline pH of the loess was a major factor in phytolith dissolution. However, they also recognized that the surface/volume ratio of the phytolith type, the amount of impurities within the silica, and the degree of silicification of the original plant cell were also important. Smaller phytoliths have less surface area when compared to their volume, and the authors noted that small rondel and trapezoid phytoliths have less surface pitting than elongates or bulliforms. The most detailed work so far on phytolith taphonomy was conducted by Cabanes and Shahack-Gross (2015). They investigated dissolution of phytoliths isolated from both four modern plant species and archaeological sediments. The phytolith morphotype assemblages from modern plants subjected to controlled partial dissolution were significantly changed from the original assemblages. So different types of phytolith dissolved at different rates and the principal factor involved seemed to be geometric surface area to bulk ratio. These results have major implications for those wishing to use phytolith analysis on archaeological samples. If some phytolith types disappear from the assemblages over time, this could markedly skew interpretation of the data obtained. In conclusion, it appears that even archaeological work focused on using phytolith morphology needs to take the chemistry of the environment and of the phytoliths into account.

International Perspectives

The work outlined in the present entry is of a very interdisciplinary nature, and it is published in a very wide range of journals by scientists from many countries. Unlike many areas within archaeology there is less limitation set by location, and researchers can be anywhere provided that they have a reasonably well-equipped laboratory. There are a number of international meetings where work on the chemistry of phytoliths is discussed. At the latest International Meeting on Phytolith Research (IMPR) held in Aix-en-Provence, France, in 2016, the keynote speaker on phytolith chemistry was Carole Perry. The Integrated Microscopy Approaches in Archaeobotany (IMAA) meeting held in Reading, UK, in February 2017 had many presentations including phytolith work, and mine looked specifically at phytolith development and chemistry. The meetings of Isotopes in Biogenic Silica (IBiS) often feature relevant work, particularly on isotopes, and the most recent meeting was in Girona, Spain, in June 2017.

Future Directions

It has become very clear that phytoliths are deposited in plants in many different locations and that these provide very different chemical environments for deposition (Hodson 2016b; Kumar et al. 2017). Just as the morphology of phytoliths varies within the plant so does the chemistry. Plant scientists are only now beginning to understand this variation. At present our incomplete understanding of the processes involved in phytolith formation is holding up progress in using

phytolith chemistry as a proxy in archaeological contexts. This has even recently affected confidence in dating with ^{14}C. With all isotopes we need a better understanding of partitioning between the phytolith and the rest of the plant. Almost certainly phytoliths in soil and sediments will degrade at different rates depending on their chemistry, but again our knowledge in this area is far from complete. What is really needed is a resurgence in interest among plant scientists and chemists in working out the deposition process in plants and how that affects phytolith heterogeneity. As I write in 2017 it appears that this may be beginning to happen, but time will tell.

Phytoliths in European Archaeological Research

Débora Zurro[1] and Martin J. Hodson[2]
[1]CaSEs Research Group. Department of Archaeology and Anthropology, IMF-CSIC (Spanish National Research Council), Barcelona, Spain
[2]Faculty of Health and Life Sciences, Oxford Brookes University, Oxford, UK

Introduction

Phytoliths are now used in archaeological research around the world. Europe was somewhat slow to take this up, but now phytoliths feature in many archaeological investigations. Ryan (2014) provides a good overall introduction to the topic of phytoliths, but here we will expand on her work and look specifically at Europe, where phytoliths are employed in a broad range of archaeological contexts. We will first assess paleoenvironmental studies and particularly those concerned with the development of agriculture. Then we will focus on ethnoarchaeological studies, an important area where phytoliths are now increasingly being used, with the aim of providing a framework for interpreting archaeological phytolith assemblages. We will then move on to consider open-air sites and cave sites, both sites of past human occupation. Finally, we will consider residue studies, assessing recent work on phytoliths on the surface of pottery, in tooth calculus, and associated with lithics (grinding stones, blades, and threshing sledges). We cannot give a full review of all this material but will provide a snapshot of phytolith research in Europe as it stands in 2018.

Definition

We will follow Ryan (2014) in only considering siliceous phytoliths. These can be defined as deposits of amorphous silica that are formed within some plant cells. In our review, we will consider all of the countries that are usually included within Europe, including Russia, but excluding Turkey and the Middle East.

Historical Background

Studies of phytoliths began in the 1800s, but their use in archaeological contexts in Europe is relatively recent. Powers (1992) wrote an excellent history of phytolith research in Europe up until that time. She reported that fairly little archaeological work had happened by 1992 and that was concentrated in three institutions: the Institute of Archaeology in London, the University of East Anglia, and the University of Sheffield. Archaeological work in Europe lagged some way behind that in America, but over the last 25 years, this situation has changed, with a move toward phytoliths being used as a standard archaeobotanical tool.

Key Issues/Current Debates

Studies involving phytoliths in European archaeological research have markedly increased. In many modern investigations, phytoliths are just one of a range of proxies used to investigate past

cultural contexts. Here we will consider the variety of phytolith studies that have been attempted in Europe.

The Paleoenvironment and Anthropized Contexts

Phytolith analyses are systematically used for reconstructing ancient landscapes both in paleoenvironmental and archaeological research. In the past much of Europe was covered by forest, but a large percentage of this has now been removed to make way for agriculture. When land is converted from forest to agricultural use, considerable changes in the plants, the soils, and in the phytolith assemblages are likely to happen. Deák et al. (2017) recently reviewed the changes that occur in soils as they are converted to agriculture and anthropization of the landscape occurs. Among the major changes that have immediate effects are the uprooting of trees, the burning of vegetation, and the disturbance of the soil profile. There follow changes in vegetation with the introduction of crops, plowing, and potentially compaction of the soil as machinery moves over it. All of these factors will affect the phytolith assemblage found in the soil. Therefore, and as a consequence of the increasing importance of concepts such as the Anthropocene in archaeological research, studies on anthropogenic soils that might not enter within a traditional definition of what is an archaeological deposit are also becoming relevant. That is the case with studies of arable fields but also for other realities such as middens, for instance. Here we will consider some contrasting examples of work in this area that illustrate the kind of investigations that can be undertaken.

Verdin et al. (2001) investigated the historical agrosystems in the Rhône mid-valley of southern France, analyzing phytoliths and other proxies in the infilling sediments of field ditches. Using this approach, they were able to observe changes in the vegetation from the Iron Age up until modern times. In this case, it was possible to detect changes in hydrology and climate as well as agricultural practices. Agriculture was evident from 2000BP at the beginning of the Roman conquest until 200BP and modern times, but there was a long gap during the Dark Ages.

Our second example comes from a very different context, medieval Brussels (Vrydaghs et al. 2007). This investigation was carried out as part of an interdisciplinary research program at Treurenberg Gate in the northeastern part of the city. The authors looked at both bulk samples and soil thin sections, which were mostly located across boundaries in the soil profile, and focused on a black horizon believed to originate around the twelfth and thirteenth centuries. They found dendriform phytoliths from barley, oats, and possibly wheat, giving direct evidence of crop cultivation. Micromorphological investigations suggested that this soil horizon had been homogenized, indicating plowing and other types of soil disturbance. Chemical analysis found a high organic matter content of the soil, probably due to intentional fertilizer additions. Physical analysis indicated that several of the soil horizons had a common sedimentary origin. Taken together, all these analyses suggest that this black horizon represented plowed land. This site is unusual as it is now very urban but was once used for agriculture. The work is also a good illustration of the advantages of using phytoliths in combination with other techniques.

In Eastern Europe, there has been a robust pedological tradition, and, accordingly, several phytolith pieces of research have been focused on the study of paleosoils associated with human occupations and on the formation processes of archaeological deposits. Together with these studies, we also find those related to the evolution of local landscapes. In this sense, anthropization of landscapes is a central topic of research, where processes of deforestation take place in parallel to plowing of new areas and the formation of agricultural soils. These changes can be identified by differences in the proportions of coniferous phytoliths (Engovatova and Golyeva 2012). To a great extent, these studies have been devoted to understanding one of the principal archaeological features of Eastern European landscapes: ancient burial mounds that are known as kurgans (Barczi et al. 2009). Our most recent example of work in this area comes from Golyeva and Svirida (2017) who worked on agricultural soils at Myakinino, near Moscow in Russia. The authors studied two

soils, one from beneath an 800-year-old burial mound and one from nearby. It was suggested that when the land is under arable usage, the phytoliths are concentrated along the plow line as they tend to gradually move down the profile over time. While many of the chemical and physical aspects of the soil plow layer had changed over the 700 to 800 years since the soil was buried, the distribution of the phytoliths was similar to the modern soil. This and the presence of dendritic phytoliths from cereal crops in the upper layer of the buried soil were clear signs of previous cultivation.

Ethnoarchaeological Studies

Despite existing debates about the different possible roles of ethnoarchaeology, we can distinguish two specific approaches. Firstly, an approach, which is often known as living archaeology, aims at understanding and studying the material culture and remains of nonindustrial societies. The second approach is a research tool that builds frames of reference (models) that allow the interpretation of the archaeological record. The construction of these models is not only achieved through the study of living societies but also by using different types of documents, being either written sources, figurative representations, or anthropological photographs. These realities and also materials, when used as references, allow the development of hypotheses that address the archaeological inquiry, that is, designing a specific sampling strategy but also choosing the proper techniques that will allow identification of the materials that are considered necessary to answer the selected research questions.

There are several archaeobotanical research programs that have been carried out with this approach and that have been extremely useful in advancing the interpretation of the archaeological record. Given the importance of agricultural societies within archaeological research, the development of archaeobotanical proxies related to the different specific steps of agricultural tasks (such as harvesting, threshing, or pounding) produced a before and after situation. The work started by G. Hillman in the 1970s on carpological assemblages gave us the basis for distinguishing these steps. Therefore, agricultural tasks can also be identified through phytolith analysis as their morphology is very often "tissue dependent." For instance, in the case of cereals (either wild or domesticated), phytoliths from the inflorescences (spikes) can be easily distinguished from those of the stems or the leaves. Ruiz-Pérez et al. (2016) analyzed the results from threshing carried out in a small village in Catalonia (Spain). A specific sampling strategy was designed to identify not only the phytolith assemblages produced by this activity but also their spatial distribution.

As part of this ethnoarchaeological approach, within the Mediterranean basin, several projects have taken advantage of the fact that there are locations in which communities still have a traditional way of life. In Greece, G. Tsartsidou and colleagues are a paradigmatic example of this approach. They recorded phytolith assemblages of an agropastoral community in order to build a reference collection that could reflect the spatial organization of the village. For this purpose, they sampled and studied different areas such as animal enclosures, floors from living areas, storage areas, hearths, and also open areas between structures. They used the information obtained to identify diagnostic features for each of the areas based on phytolith morphotypes and richness, among other features (see Tsartsidou et al. (2009) and Friesem et al. (2014)).

More recently, we are witnessing the development of the concept of anthropic markers. These can be defined as the models based on ethnographic information that address archaeological reality through a multiproxy approach, mostly referring to materials that are non-visible to the naked eye. With this method, phytolith analyses often appear combined with other analyses such as those for organic matter content, multielement analyses, chemical residues, or other archaeobotanical remains. Beyond the application of the anthropic marker concept, multiproxy approaches in which phytolith analyses play a pivotal role are becoming widespread (mostly within prehistorical archaeology).

Finally, experimental archaeology also aims at creating frames of reference for understanding the

transformation of materials through work investment. One of the most important features that we find in archaeological sites is fireplaces. To correctly interpret possible changes in phytoliths caused by burning as well as composition of the phytolith assemblages, controlled experiments have been carried out (Albert and Cabanes 2007). Phytolith analysis is a useful tool to understand the proportion of wood versus other plant material present and that were also used as fuel. Therefore, possible different functions of hearths which were used not only to produce heat, but light or smoke, or to clean surfaces, can be identified.

Open-Air Sites

Open-air sites include a wide range of different archaeological contexts, from Paleolithic campsites to sources of raw materials, past agricultural terraces, or urban villages, among others. Consequently, the questions related to plant management that can be addressed are multiple.

From what we know of history and ethnography, human communities impact their surrounding environments beyond the use of dwellings and their adjacent spaces and the production of agricultural landscapes (see section "The Paleoenvironment and Anthropized Contexts"). For the identification of these areas, the study of organic matter and plant remains becomes essential. That is the case for Birka, a Viking town that existed between AD 750 and 975 on the Baltic Sea (Risberg et al. 2002). In this site, the authors studied a midden area and expected this refuse area to be formed by "(. . .) latrine cleanings, cuttings of shore vegetation, cleaning of ditches and storage areas, and domestic animal dung." To carry out this study, multiproxy research, including phytolith analysis, was designed.

Regarding campsites and villages, which constitute the vast majority of open-air archaeological sites, the use of phytolith analysis as a proxy for distinguishing the use of spaces is the major trend. Within open-air sites, several archaeological features that are found in caves are also present, such as hearths or pits. However, in these contexts, very often there is an obvious structuring of space as remains or whole pieces of pavements and architectural elements are preserved. In specific contexts, walls or even whole villages and different types of buildings are also evident, and entire ancient cities can be studied. In this case, phytolith analysis is used to study features that can be explained as part of plant management dynamics, such as those regarding cereal storage or processing or their appearance in graves, for instance (Hansson and Bergström 2002). But there are also explorative analyses that aim at understanding how space was used, trying to link particular activities to specific spaces or areas of the sites. This can be done at different scales of analysis, which range from habitation units such as rooms (intra-site analysis) to the macroscale (at site level). All these different scenarios imply different sampling strategies that need to be specifically designed to reveal the variability (regarding both richness and distribution) present in that reality under study.

In European archaeology, these studies still remain at an explorative level, in which phytolith analysis is tested and applied mostly:

– To understand specific features (frequently hearths in ancient contexts and structures related to cereal storage for later periods) (Braadbaart et al. 2012; Balbo et al. 2015).

– To carry out controlled sampling: these strategies are devoted to understanding whether phytolith assemblages coming from those specific features or as residues from artifacts are somehow background noise of the site or can be interpreted as specifically linked to activities carried out in concrete locations with specific artifacts (see Tsartsidou et al. 2015).

– As a tool used across single spaces in which we expect plants to play an important role, so that activities can be identified and spaces tagged regarding their socioeconomic function (see Milek and Roberts 2013)

In this last case, open surfaces can be sampled following different strategies that may unveil the spatial patterns from plant processing, matting, and cattle housing or from remains from collapsed roofs, among others. These sampling strategies are still being tested, and the extent to which uncertainty is managed through them still needs to be developed and properly understood.

Cave Sites

The study of human occupation in caves is paramount for the understanding of European prehistory. In central Europe as well as in the Mediterranean basin, caves are a common element within the landscape. Both caves and shelters have been used by human populations for millennia for different purposes, which might include not only habitation but the use of caves as spaces for storage, as barns, for ritual activities, or as spaces for inhumation. Therefore, a variety of archaeological materials may be found in caves, and these activities are often much greater than those that archaeological studies usually record. Besides, the reoccupation of caves has produced long and complex stratigraphic sequences that might span from the middle Paleolithic to Medieval or even later times.

Compared to open-air sites, caves are closed contexts, so the archaeological approach toward them is slightly different than that for open-air sites, and they are usually considered anthropic spatial units per se. In spite of this, non-anthropic sedimentation and plant input also occur, so caves are often not only the record of past human history but can also be explored as archives of environmental and climatic change. However, there has been much debate about using phytolith assemblages from caves as the basis for paleoenvironmental reconstructions. In archaeological sites, part of the plant input constitutes a filtered selection from what there is in the landscape. That means that the anthropic contribution adds to an existing baseline of phytoliths (as a background noise) that is part of preexisting sediments. Therefore, in spite of being closed contexts, in cave archaeology it also becomes paramount to distinguish anthropogenic versus non-anthropogenic phytolith assemblages. The proportion of phytoliths per gram of sediment or AIF (the phytolith richness) can be used in some contexts as a proxy of human occupation. In ancient contexts where little evidence about plant use may be found, such as those corresponding to or before Upper Paleolithic times, the study of diagenesis becomes essential as it affects the calculations that produce a phytolith per gram figure. The investigation of diagenesis allows for understanding of the mineralogical composition of the deposits that would produce changes in the soil (see Karkanas et al. 2002).

Phytolith analysis has been used within cave archaeology to accomplish different aims, the primary focus being the identification of plant input of anthropic origin. This becomes especially relevant to hunter-gatherer occupations in which no other archaeobotanical remains might have been found. Even though until now most phytolith analyses have addressed phytolith preservation and diachronic changes through time, spatial patterning is gaining weight. In these cases, the study of bedding layers as well as the study of fireplaces and general sediments has gained much interest during the last few years (see Cabanes et al. 2010). For later periods, the study of caves as livestock enclosures and phytolith analyses of manures carried out together with spherulite and multielement analysis are throwing much light on changes in animal grazing through time (Alonso-Eguíluz et al. 2017).

Residue Studies

Phytoliths are often found in residues associated with human activities. Three commonly investigated residues are found on the surfaces of pottery, included with calculus on teeth, and associated with implements such as lithics or macrolithics. While most residue studies on teeth and lithics have been carried out in Africa, Australia, America, and the Middle East, in Europe residue studies have mostly involved pottery. However, in this section we will provide European examples from all three contexts as it is quite likely that work in the less popular areas will increase over time.

When people cook in pots, phytoliths may be left behind in the residue. Sometimes plant material is boiled, and sometimes it may be burnt. In many cases phytoliths will be concentrated in the residue which are then found in the carbonized food deposits coating the pots. Even apparently unpromising materials with low phytolith concentrations can provide information when the phytoliths are concentrated. So Hodson et al. (2001) were able to obtain phytoliths from pasta by boiling large amounts in acid. They were then

able to determine that the phytoliths originated from durum wheat (*Triticum durum*) rather than bread wheat (*Triticum aestivum*), as the papilla phytoliths of the latter are larger. Although not in an archaeological context, this is an analogous situation and illustrates the point that phytoliths can be concentrated from food in which they are low in concentration. In archaeological work, Saul et al. (2013) provide a good example of the use of phytolith analysis on residues from pots used in cooking from a number of sites in the western Baltic. They were particularly interested in the spread of spice usage across Europe and found phytoliths from carbonized food deposits on prehistoric pottery dating from 6100 cal BP to 5750 cal BP. The phytolith morphologies were identified as coming from modern garlic mustard seed (*Alliaria petiolata*). The authors considered that this was the first evidence for the spicing of food in European prehistory.

Dental calculus forms at the base of teeth along the gum line in animals and humans. It mostly consists of calcium phosphate but also contains bacteria, remains of food, and other compounds. It is hard and durable, constituting a sealed context where no contamination can take place and has been found to contain phytoliths. Much of the work on phytoliths in dental calculus has occurred outside Europe, but Power et al. (2015) provide a good example of what is possible. They worked on human dental calculus isolated from the teeth of an individual known as the "red lady" who was buried in El Mirón Cave in Northern Spain. The phytoliths found in the calculus included long-cell psilates, cylindroid psilates, hairs, and a mesophyll form. Some of these appeared to be from monocots. The calculus was unusual in that it also contained a variety of unsilicified plant cells, starch grains, fungi, and pollen. The authors suggested that the stability of the calculus microenvironment was probably responsible for the increased variety of findings, as usually only starch grains and phytoliths are found. It was concluded that the "red lady" had a diet that included plant material during the Magdalenian period in Northern Iberia, and this was not confined to meat obtained from hunting.

For many years, Patricia C. Anderson has pioneered work on phytoliths and cutting instruments such as stone blades and threshing sledges. In some cases, phytoliths become attached to the stone blades as cereals are cut, and continual cutting can give the blades a gloss. The use of threshing sledges (tribula) to cut straw leads to the production of silica skeletons (groups of phytoliths that keep their original anatomical connection) that have distinctive cut edges. Much of that work has focused on the Middle East and North Africa, but Anderson has also applied her techniques to European contexts. Anderson and Whittaker (2014) review this work, concentrating most attention on Mesopotamia but also including archaeological investigations in Bulgaria, Cyprus, France, Spain, and Turkey. A considerable amount of Anderson's work has been experimental, cutting modern plant material with newly fashioned stone blades and constructing tribula or finding places where these threshing sledges are still used and obtaining samples from these sites. Using these techniques Anderson and her co-workers have been able to show how agricultural practices diffused from their origins in Mesopotamia into Europe in the Neolithic period.

International Perspectives

Despite a relatively slow start (Powers 1992), the use of phytoliths in archaeological research in Europe has grown rapidly in the last 25 years. The first International Meeting on Phytolith Research (IMPR) was held in Madrid in 1996, and of ten meetings so far, eight have been held in Europe (two each for Spain, France, and Belgium and one each in the United Kingdom and Russia). The last meeting took place in Aix-en-Provence, France, in September 2016. Arising from these meetings, three edited books and three special editions of the journal *Quaternary International* have appeared (see Further Readings). The Integrated Microscopy Approaches in Archaeobotany (IMAA) meetings held in Reading, UK, in 2016 and 2017 had many presentations including phytolith work, and further meetings are planned.

Future Directions

There are many issues that need to be further developed in phytolith research. These include the development of methods aimed at understanding anthropic versus natural input in archaeological contexts. We also need to disentangle which plants were used as raw materials and with which tools (when analyzing phytoliths as residues). Another question relates to the differential production of phytoliths in dicots versus monocots and how to eliminate this bias and standardize data.

When considering Europe, there is a specific need for creating reference collections regarding the use of plants other than cereals in the past. These would include those wild species that are usually gathered and that mostly appear in pre-agricultural contexts but also several other species that have been extensively used for basketry, textiles, and other items. Therefore, there is the need to create ad hoc reference collections for European contexts, which include a wide chronology and several different landscapes and plant resources, ranging from the Arctic to the Mediterranean basin.

Finally, deforestation of Europe during the extension of agricultural practices has been mainly addressed until now through anthracological and palynological studies, and we still need to understand if phytolith analyses will be able to offer new insights into this deep anthropization of European landscapes. This may happen either through identifying phytoliths whose presence or absence might be a diagnostic of this process or through the creation of indices as has been done in other areas of the world to understand changes in vegetation cover.

Phytoliths in Islamic Archaeology

Sofia Laparidou
Department of Anthropology, University of Texas at Austin, Texas, TX, USA

Introduction

The study of Islamic rural history and archaeology is a fast-growing focus for archaeological science. Despite efforts by many researchers to incorporate environmental studies, such as archaeobotanical analysis, into their methodological framework, these studies are limited and non-systematic. Information regarding local economic decisions, independent from state control, which represent the local resilience of medieval subsistence farmers, is missing. It is therefore important to develop a better understanding of shifts in agricultural investment and intensification of production, and the life of subsistence farmers in relation to environmental, political, and economic change during the early, middle, and late Islamic periods.

Definition

Sediment analysis for phytolith extraction can be used to inform the issue of agricultural systems during the Islamic periods and to reveal risk-minimization strategies adopted by medieval peasants as mitigating factors against political and environmental turmoil. The adaptive decisions of peasants can be investigated using micro-botanical data deriving from different environmental regions and multi-temporal Islamic archaeological sites. It is important that data for the purposes of this analysis be derived from different environmental zones. Without downplaying the political economic forces that shaped the social and ecological history of the Islamic periods, the role of regional agricultural and pastoral production for state profit and for local subsistence can be assessed with the use of phytolith data. Such research considers regional agricultural practices adopted during and after the agricultural revolution of the early Islamic period (Watson 1983) and aims to investigate what happened in the periods following these important changes to the Islamic agrosystem.

Key Issues

Phytoliths are particles of amorphous silica that are formed with the absorption of ground water by the plants when living. Silica (opal) is deposited in the cells of plant epidermal tissue, and the shapes of these cells define the phytoliths' morphology. For the purposes of archaeological analysis and interpretation, the recovery and identification of two major types of phytoliths is necessary: single-cell and multi-cell phytoliths. Single-cells are individual cells formed within the plant, and multi-cell phytoliths are conjoined single-cells that form silica skeletons of adjacent cells of the epidermal tissue of grasses (Rosen and Weiner 1994). In order to assess the issue of agricultural production during the Islamic period, the identification of particular phytolith morphotypes is used for interpretation. First, plant families and subfamilies are identified using single- and multi-cells, with the identification down to genus of major economic plants using multi-cell phytoliths. Second, the identification of different plant parts is used in order to identify by-products associated with different crop-processing stages following the conclusions of ethnographic work conducted by Hillman on macro-botanical remains (Hillman 1984) and the study of Harvey and Fuller (2005) on the identification of crop-processing stages through macro- and micro-botanical remains. Phytoliths can in this way offer information on agricultural activities and processing by-products and allow the exploration of agricultural and pastoral pursuits.

Phytoliths' direct deposition in sediments makes them excellent proxy data for archaeobotanical analysis. As inorganic matter, their persistence against destruction in different environments such as temperate, cool climates, and arid and semiarid conditions increases the possibility of their preservation when other

archaeobotanical and paleoecological evidence may decay unless charred (Rosen 1999; Piperno 2006). However, not all plants produce diagnostic phytoliths. Many families and species share morphological characteristics making their identification through the phytolith record difficult or impossible. For the purposes of archaeological analysis and interpretation, emphasis has been given to the study of the identification of major economic plants and crops such as maize (Piperno and Flannery 2001) and others useful for the purposes of the study of the Islamic periods: Poaceae family cereals, some wild cereals and dates (Rosen 1992, 1999; Rosen and Weiner 1994), rice (Pearsall et al. 1995; Harvey and Fuller 2005), millets (Harvey and Fuller 2005), Cucurbitaceae family plants (Piperno et al. 2000), and a number of Cyperaceae family plants (Ollendorf 1992). Dicotyledonous plants (woody trees and shrubs) offer limited identification potential (Bozaarth 1992), while phytoliths in fruits and pulses likewise present limited possibilities for identification.

Current Debates

Phytolith data from selected Islamic archaeological sites can produce a better understanding of the historical ecology and agricultural practices adopted during the Islamic periods. More specifically, micro-botanical analysis can assess the intensity in habitation and land use through identification of agricultural and pastoral pursuits or intensification of agriculture through irrigation signals and diversification (Rosen and Weiner 1994). Experimental work done on phytoliths of Emmer wheat has explored the possibility of using phytoliths as evidence of past irrigation systems. Counts of more than 10 and 100 conjoined single-cells were formed in irrigated planted cereals (Rosen and Weiner 1994). Since then, further work has been done to explore further planting and growing conditions of cereals and the effect of irrigation and rain water on the formation of phytoliths (Mithen et al. 2008). Experimental studies supported the results of Rosen and Weiner, but yet posed questions of how soil chemistry, evapotranspiration rates, and sub-, optimal, and over-optimal irrigation affect phytolith formation in wheat and barley species and in different parts of the plant. Phytolith data can provide information for local practices, subsistence, identification of activity areas such as for crop processing, animal husbandry practices, and other cultural activities and aspects of the medieval economy (Rosen 1999; Piperno 2006). Once more data are produced from medieval Islamic sites in different regions, phytoliths may shed light on similarities and/or differences in subsistence, economy, settlement cycles, and microenvironments of sites from different geographic regions and environmental zones.

Phytolith data that derive from medieval Islamic centers and villages seek to test two hypotheses. First is to trace the continuity of the early Islamic agricultural revolution, or "Green Revolution," as defined by Watson (1983) regarding agricultural intensification through the production of major cash crops and other crops during the periods of study. This can be done through the identification of phases of agricultural intensification of production. Do we see the peak and decline of agricultural intensification after the period of the Green revolution? The idea of an Islamic agricultural revolution that happened with the beginning of the Islamic era was proposed by Watson. Watson claimed that the early Islamic world contributed to the global history of agriculture (700–1,100 CE). He suggested that the Middle East, North Africa, and Spain underwent an agricultural revolution. This period brought two major changes in agricultural and landscape history. One was the intensification of production through the spread and cultivation of new major cash and staple crops. Most of these crops came from East or South Asia, and they were not known in the Middle East and/or the Mediterranean. The example of sugarcane is crucial and has been central to historic and archaeological studies trying to trace its diffusion, production, and state or domestic use (Watson 1983). Like sugarcane, rice diffusion and intensive cultivation during the Islamic period is of great interest.

Intensification of production did not come only from intensified agriculture of cash crops, such as

sugar, cotton, and rice, but also with the rise in varieties of crops and diversification of production. Watson (1983) lists 18 crops, which he claims were incorporated into the economy and diet of the Middle East and the Mediterranean due to Islam, although most of the crops existed before the period of the Green Revolution. The new crops were diffused from tropical climates of the East and incorporated into the production economy of the Middle East. A second change resulting from the Islamic agricultural revolution was the shift to double cropping and the introduction of highly irrigated summer crops. Of course, the increased need for water by these new crops led to extensive investment and reuse of existing irrigation systems. Watson claimed that crops were diffused from India and Southeast Asia, through a huge connection network relating to maritime trade, along with the "manuals" and knowledge for their cultivation. In addition, emphasis was given to the expansion of free-threshing durum wheat and drought-resistant sorghum that changed the production and diet of the medieval period. However, Watson based his thesis on textual evidence and theories of diffusion, and although his conclusions are impressive and rational, his thesis should be supported through archaeobotanical evidence along with the study of medieval texts and has thus been reevaluated (Butzer 1985).

Secondly, phytolith data can be used to suggest the resilience of subsistence farming by local people during the Islamic periods, during and after the period of the Islamic agricultural revolution using samples from different sites in different geographical regions. This method offers the opportunity to compare pastoral and peasant land use and subsistence among the areas under study. Thus, phytolith data can offer a different insight into adaptations to different environmental zones during periods of climatic and political turmoil during the Islamic periods and a new insight into the resilience strategies of medieval farmers in different regions of Jordan at that time. Identification of single-cell phytoliths that represent subfamilies of the Poaceae family, Pooideae, Chloridoideae, and Panicoideae (Twiss 1992) and plants of the Cyperaceae family, can be used for the description of sites' microenvironments and to show whether local environmental conditions favored crop production. In general, C3 plants are indicative of more moderate climatic conditions and produce rondel-shaped short cells. Panicoid grasses generally grow in warm and humid environments and produce bilobes and cross-shaped phytoliths. Chloridoideae, which indicate dry land grasses and warm and dry habitats, create saddle-shaped short cells (Twiss 1992; Piperno 2006). Looking at phytolith densities of C3 versus C4 grasses present on sites during the Islamic periods could shed light on this direction of research.

Also, phytolith data from Islamic sites aim to identify two major economic plants, wheat and barley, given that identification is possible using specific morphological criteria of multi-cell phytoliths (Rosen 1992). As they are main staples, and in the case of wheat, cash crops of the period of study, their identification is crucial for describing the continuity of agricultural production. They can be identified securely as they have been well studied by phytolith scientists (see Rosen 1992) and can contribute to the identification of these major economic plants of the medieval period and trace irrigation signals. Husk and stem phytoliths can be counted and used as indicators of the by-products of crop-processing stages in order to explore whether the sites under study produced their own crops or imported grains or other crops (Hillman 1984; Harvey and Fuller 2005).

In addition, phytolith and macro-botanical data acquired from multi-temporal medieval sites of different environmental zones, from a variety of contexts with an expected high yield of phytoliths (Rosen 1999), can shed light on the subsistence economy characterizing different regions. Information about the main agricultural crops produced in the sites under study in different regions during the Islamic periods can be provided, in addition to whether crop selection changed through time.

The Social Significance of Phytoliths for Islamic Archaeology and the Importance of an Interdisciplinary Approach to Rural Islamic History and Archaeology

The state-controlled agricultural economy and the subsistence economy of a site can be reflected in

the phytolith record based on the sampling strategy adopted. Samples may derive from both state-controlled buildings and subsistence farmers' buildings. Thus, phytolith data can be used as indicators for state-controlled access to irrigated crops, as well as for a more opportunistic agriculture adopted by subsistence farmers. An example of such a site is Tell Hisban, Jordan, where the villagers' farmhouses and animal pen, as well as the fourteenth-century governor's storeroom and sixteenth-century governor's house courtyard, were sampled for phytoliths. At Tell Hisban, both domestic and administrative-related buildings have been excavated and sampled for phytolith analysis, shedding light on the political ecology of the period of study, but such contexts are not always available. Thus information from medieval texts becomes invaluable.

Walker (2011) investigates and explains parameters of medieval society in Jordan that emphasize the regionally distinct character of its districts and the selective investment and decisions of the Mamluk state. She suggests that local histories should be reconstructed in order to understand the forces that shaped the socioeconomic transformation that took place between the fourteenth and sixteenth centuries. First, she addresses the issue of Jordanian tribes as a political force. The Mamluk state aimed for strong ties with and allies within the local tribes, and this was ensured with sultanic visits and assimilation, tactics that were not always successful in controlling local rebellions and complaints especially during periods of environmental and economic stress. Local tribal history constitutes one aspect of regional histories affecting the relationship of the state with its provinces and by extension Mamluk investment in the peripheral state of Jordan. The different political, cultural, and environmental regions of Jordan, where the Jordanian people/tribes resided, are described according to their urban character through information from Mamluk *waqfiyyat*, court documents (*shari'ah*), and sixteenth-century tax registers along with their agricultural and pastoral potential and production. The rural character of the country is dominant in the description of these texts, and the concept of a city is absent for Mamluk and Ottoman South Syria, apart from the castle-towns. However, Walker presents archaeological work and the results of surveys that have been employed in order to understand the nature and extent of the "villages" of Mamluk and Ottoman Jordan mentioned in *waqfiyyat*. Most importantly, the archaeological work she supports will help to reconstruct the everyday life of commoners, in addition to information from medieval court documents, something that is missing from the contemporary administrative, economic, and legal sources. The focus of political economic history is now shifting towards the investigation of local environmental parameters, such as the quality of agricultural land, soil properties, local rainfall variations, and local land-use changes as found in the archaeological record. Syrian chronicles and Ottoman registers are also used in order to reconstruct peasants' lives, agricultural history, and how the rural history of the middle and late Islamic periods in Jordan can shed light on the issue of demographic decline by the end of the Mamluk Era. Walker's work takes an interdisciplinary approach to this phenomenon of "decline" that emphasizes the regional character of Jordanian society as shaped by its political, ecological, and economic environment. The analysis of phytolith data is another strand that can and should be added to this multidisciplinary research.

Future Directions

It is necessary to incorporate the study of phytoliths into research that uses archaeobotanical analysis for identifying the everyday life practices of peasants. Walker (2011) offers an interesting approach, which combines archaeological work conducted on the major cities and villages accounted in registers and waqfiyyat of the Mamluk period, as well as in Ottoman tax registers of the early sixteenth century, in order to investigate the regional implications of administrative control over local production.

In sum, phytoliths can provide an innovative contribution to the study of Islamic rural history and archaeology. Future research will shed light on the investigation of local agricultural regimes

as key factors transforming regional social, demographic, and ecological history with the use of multiple lines of evidence alongside phytolith analysis and interpretation, such as archaeological, environmental proxy data, as well as documentary data such studies are under way (Cordova et al. 2005; Lucke et al. 2012). A systemic analysis of all these sources can inform land-use change and environmental and climatic histories of the medieval Islamic periods.

P

Pickersgill, Barbara

Charles R. Clement
Instituto Nacional de Pesquisas da Amazônia, Manaus, Amazonas, Brazil

Basic Biographical Information

Barbara Pickersgill is a British horticultural botanist and geneticist. She was born on 13 May 1940 and raised in Yorkshire, England, and obtained her B.Sc. degree in Horticultural Botany from the University of Reading in 1962. Immediately

thereafter she pursued her Ph.D. in Botany at Indiana University, Bloomington, under the supervision of Charles B. Heiser, Jr., with a thesis entitled *The Variability and Relationships of Capsicum chinense* Jacq. that she defended in 1966. Upon her return to England, she was appointed lecturer in the Department of Agricultural Botany at the University of Reading, UK. She retired in 2005.

Barbara Pickersgill's work with *Capsicum chinense* stimulated a lifelong interest in determining the origins and dispersals of Neotropical crops, later expanded to the rest of the world with her numerous students. Her interests in the use and conservation of crop genetic resources also involved her with the International Board for Plant Genetic Resources, now Bioversity International. She participated in expert consultations, funded by the Board, to plan and execute *Capsicum* collection, characterization, evaluation, and use strategies for collections held at both the Centro Agronómico Tropical de Investigación y Enseñanza, Turrialba, Costa Rica, and the Centro Nacional de Recursos Genéticos, Brasília, Brazil.

Soon after returning to Reading, she was invited to act as botanist for the Ayacucho Archaeological-Botanical Project, Peru (1969–1971), and later for the Cuello Early Maya Archaeological Project, Orange Walk Town, Belize (1979). These activities introduced her to many of the Neotropical archaeologists working with crop origins and dispersals and involved her in numerous symposia over the next decades.

While based at the University of Reading, Barbara Pickersgill was appointed by the Royal Society to be a visiting professor at the Departments of Agriculture and Biology of the University of Papua New Guinea, Port Moresby, in 1978. She was also invited to offer undergraduate or postgraduate courses in Italy, Spain, the Netherlands, and Cuba. She also acted as external examiner for Ph.D. theses at eight British and one Irish universities.

In 1993, Barbara Pickersgill was awarded the Linnean Gold Medal for Botany, became a Fellow of the Linnean Society of London, and was elected a Fellow of the Institute of Biology. She was later elected President of the Society for Economic Botany (2000–2001).

Major Accomplishments

Barbara Pickersgill's early work with the cytogenetic and morphological variation in *Capsicum* complemented work by Charles B. Heiser, Jr., her doctoral supervisor, and W. Hardy Eshbaugh, another Heiser student, and was instrumental in delimiting species and species complexes within the genus, as cytogenetics is a much more precise technique for species analysis than is morphology, especially in such morphologically variable domesticates as *C. annuum* and *C. chinense*. Heiser and his group confirmed that Native Americans domesticated five *Capsicum* species and distributed three of them widely. The three widely distributed species, *Capsicum annuum*, *C. chinense*, and *C. frutescens*, form a complex, because their probable wild ancestor is also widely distributed. The group confirmed that *C. annuum* originated in Mexico and was distributed southward, while *C. chinense* originated in Amazonia and was distributed northward; *C. frutescens* is less well understood, although its distribution is nearly as wide. *Capsicum baccatum* originated in the low-level Andes of Bolivia and Peru and was distributed northward to Colombia and southward to the warm temperate areas of the southern cone, while *C. pubescens* originated in the higher Andes. These studies were immediately relevant to archaeologists, since they may allow species-level identification by the combination of seed, fruit, and fruitstalk morphology and known distributions and provide criteria for distinguishing domesticated from wild peppers (Pickersgill 1969a, b).

During the 1960s and 1970s, the taxonomy of cultivated plants was often confused, because taxonomy was based primarily on morphology. With the inclusion of cytogenetics, the taxonomy of crops could be clarified (Pickersgill 1977), allowing curators of collections of genetic resources and archaeologists to work with better information. Since then, molecular genetic techniques have become powerful tools in taxonomy and domestication studies (Pickersgill 2007).

With her students, Barbara Pickersgill has delved into the origin and dispersal of the common bean (Chacón et al. 2005, 2007), peanut,

and the domestication process in Mexican cacti (Casas et al. 1997), as well as into Paleotropical crops, such as winged bean and bananas. This wide range of studies has given her a privileged view of crop domestication, which has resulted in recent reviews of Neotropical crops (Pickersgill 2007) and of the domestication process itself (Pickersgill 2009). Even after retirement, her collaboration with her Mesoamerican students has resulted in further publications on *Capsicum* (Pickersgill 2016a, b), domestication in the Neotropics (Pickersgill 2016c, d), and an important review of the genomics of parallel versus convergent evolution in Neotropical crops (Pickersgill 2018). During her career, she published more than 60 papers and book chapters, many of which are widely cited by archaeologists, as well as plant breeders and curators of crop genetic resources.

P

Pig: Domestication

Linus Girdland Flink
Earth Sciences Department, Natural History Museum, London, UK

Basic Species Information

Pigs belong to the genus *Sus*, the family Suidae, and the order Artiodactyla, which are even-toed ungulates (hoofed mammals). Unlike other domestic ungulates such as sheep, goats, cattle, and llamas, pigs are opportunistic omnivores that feed primarily by rooting and scavenging. Wild pigs easily adapt to new environments and inhabit a wide variety of habitats and ecosystems (Groves and Grubb 1993).

Other common names for pig include *swine* and *hog*:

Boar: male pig
Sow: female pig
Piglet: baby pigs

The common domestic pig is a domesticated form of the Eurasian wild boar (*Sus scrofa* sp. Linnaeus, 1758). *Sus scrofa* sp. is divided into four distinct groups (the Western, Indian, Eastern, and Indonesian/Sundaic races) and consists of up to 17 subspecies (Groves and Grubb 1993). *S. scrofa* is one of the most widespread and numerous mammals in Eurasia, and its natural geographic range covers most of the Eurasian continent stretching from West and Central Europe (including Scandinavia and the UK, where it has been reintroduced after extinction) and North Africa in the West to Eastern Siberia, Malaysia, and the Indonesian Islands in the East (Fig. 1) (Groves and Grubb 1993).

Feral or wild pigs are often found outside the native range of *S. scrofa* as a consequence of human agency (translocations of wild or domestic pigs). Large feral pig populations are particularly common in South and North America (where it is known as the *razorback*), Papua New Guinea, New Zealand, Australia, Sardinia, and Corsica (Albarella et al. 2009).

Pig: Domestication, Fig. 1 A simplified depiction of the native distribution of *S. scrofa* (*light gray*) across Eurasia (Redrawn from Groves and Grubb (1993) and Larson et al. (2011)). Uppercase letters depict the two major centers of independent pig domestication in Eastern Anatolia and East Asia (**A** and **B**, respectively). Lowercase letters (**c**–**h**) indicate putative domestication centers where it remains unclear to which degree domestication was independent (**c**: Europe, **d**: Italy, **e**: South Asia, **f**: Peninsular Southeast Asia, **g**: Southern Yunnan Province, Northern Vietnam, Northern Laos, **h**: Lanyu off the coast of Taiwan). Thick dashed lines highlight the four major groups of *S. scrofa* subspecies and their approximate geographic distribution. Thin dashed lines across Central Asia depict an area where *S. scrofa* is rare or absent

Domestic pigs display a large variety of morphological and behavioral traits compared to their wild predecessor. The most prominent characteristics include changes in the reproductive cycle, reduced brain size, floppy ears, shortening of the snout and tooth-row, general reduction in size (although both giant and dwarf variants occur), a large variety of coat colors, wavy and curly hair (see the curly coated pig breed Mangalitsa), and rolled or curly tails (Groves 1999; Albarella et al. 2009).

Morphological changes in teeth and long bones are good markers for identifying domestication in archaeozoological materials. Measurements of the M2 and M3 are particularly useful for telling apart wild and domestic pigs (Albarella et al. 2009).

The relationship between humans and pigs extends back more than 10,000 years (Larson et al. 2011). Many pig populations and especially prehistoric ones are difficult to define as either fully domesticated or completely wild. This is due to the fact that humans have managed and controlled morphologically and behaviorally wild populations and kept domestic pigs under varying degrees of control since at least the Early Holocene (Albarella et al. 2009; Larson et al. 2011). Modern anthropological data from Papua New Guinea reveal that humans both manage and control both wild and domestic populations simultaneously. The morphological and biometric differences between these populations have been substantially reduced because people often breed their domestic pigs with wild boar (Redding and Rosenberg 1998).

Despite methodological difficulties, archaeological and genetic data clearly demonstrate that pig domestication occurred independently in at least two major geographic regions: West Eurasia and East Asia (Fig. 1) (Larson et al. 2005), though pigs may have been domesticated up to nine times across Eurasia during the Holocene (Fig. 1) (Larson et al. 2011). The extent to which these domestication processes were truly independent, and to which extent they represent wild-domestic hybridization, remains uncertain (Larson et al. 2011).

Pig domestication was integral to the Neolithic revolution. The earliest archaeozoological evidence of pig domestication in West Eurasia comes from several archaeological sites in the Near East and dates to approximately 10,000 BP (Fig. 1) (Larson et al. 2007). Archaeozoological and genetic data show that domestic pigs possessing genetic signatures previously endemic to the Near East were introduced to Europe at least 7,500 BP. Once introduced to Europe, local domestication or extensive introgression gradually replaced the genetic signature from the Near East with those of the local European wild boar. The introgression appears to have been widespread as domestic pigs possessing haplotypes endemic to Italy and the northern Adriatic coast appear in the archaeological record subsequent to the earliest introduction from the Near East (Larson et al. 2005, 2007).

In East Asia, archaeozoological and genetic data reveal complex patterns of local domestication. The earliest evidence of pig domestication comes from archaeological sites along the Yellow River (and to some extent the Yangtze River) in Central China dated to approximately 10,000–9,000 BP. Unlike the patterns of genetic turnover in Europe and the Near East, ancient and modern genetic data suggests long-term genetic continuity between early and modern domestic pigs (Larson et al. 2010, 2011).

The remaining putative domestication centers (Fig. 1) have been identified primarily through modern genetics (but also through the combination of geometric morphometrics and genetics). In many cases, modern genetic data reveal unique genetic signatures possessed by both local domestic pigs and local wild boar (Larson et al. 2010). These include several locations in Europe (see above), Peninsular Southeast Asia, and surrounding areas in southern China, Northern Vietnam and Northern Laos, South Asia (Indian subcontinent), and the Lanyu islet off the coast of Taiwan. Until ancient DNA becomes readily available from these locations, the demographic history of these populations remains hypothetical (Larson et al. 2011).

Pigeon Pea: Origins and Development

Eleanor Kingwell-Banham and Dorian Q. Fuller
Institute of Archaeology, University College London, London, UK

Basic Species Information

Pigeon pea (*Cajanus cajan* L. Millsp.), also known as *toor*, red gram, Congo pea, no-eye

pea, *kadios*, and tropical green pea, is a legume grown in tropical and semitropical regions across the Old and New Worlds. While New World cultivation is relatively recent, pigeon pea is a traditional crop of South Asia and western and central Africa and an African diaspora in the Caribbean. It is grown as a food and/or fodder crop and has additional use as a green manure crop.

Pigeon pea can grow up to around 4 m in height. It is a drought-tolerant crop and can grow with less than 300 mm annual rainfall due to its long tap roots, although it prefers 600–1,000 mm. The ideal temperature range for pigeon pea is 18–30 °C; however it can resist temperatures over 35 °C. It is therefore a crop particularly suited to the drier tropics. It can be grown at altitudes of up to approximately 2,000 m, as long as the temperature is not too low. The plant takes between 6 and 11 months to reach maturity usually, but some newer varieties take only 3–4 months. Pigeon pea is rarely grown as a primary crop and is often cultivated alongside grain crops such as millet, sorghum, or rice (Kachroo and Arif 1970).

The crop can be harvested as either green pods, which can be used as fresh vegetables, or dry, just before the mature pods shatter. Rather than being fully non-dehiscent, domesticated forms have delayed dehiscence. Harvesting dry pods tends to be done with a sickle in large areas of both Asia and Africa. The plant is then left to dry further in the sun before threshing is carried out. It is then winnowed and the clean peas are collected (Fuller and Harvey 2006). This simple process means that the peas are less likely to appear in the archaeological record than crops which require extended processing sequences. Splitting the peas, however, may increase their chances of preservation as waste from milling (including fractured peas) may be burnt. Split pigeon peas are a popular pulse in India, used to make *toor dal*. Aside from its use as a food crop, the plant can be used as a host for lac-producing scale insects (Krishna 2010). Lac, a red resinous substance which can be used as a dye or as a varnish, is predominantly produced in South and Southeast Asia.

Major Domestication Traits

Identification of pigeon pea seeds can be quite straightforward. The split peas often show a distinctive apostrophe-shaped shoot bud within the embryo (Fig. 1). Whole peas range in shape, from more rounded to fairly square, but all tend to be flat on the hilum end. The distinction between

Pigeon Pea: Origins and Development, Fig. 1 *Line drawings* of pigeon pea pod and seed, clockwise from *top left*: pod; basal view showing hilum, including internal anatomy such as distinctive plumule; lateral view with protruding strophiole of hilum visible above; and cross section showing embryo plumule shaded

wild and domesticated peas is difficult. However, wild peas tend to be slightly smaller and flatter than the domestic species. In addition, wild species have a greatly increased appearance of a raised ring around the hilum (Fuller and Harvey 2006).

Timing and Tracking Domestication

Pigeon pea was domesticated from *C. cajanifolia*, populations of which occur across eastern Peninsular India (Fig. 2; see discussion in Fuller and Harvey 2006; Kassa et al. 2012). While reported finds of

Pigeon Pea: Origins and Development, Fig. 2 Distribution map of wild *Cajanus cajnifolia* together with archaeobotanical finds of pigeon pea in India. The location of wild pigeon pea at the southern margins of the wild rice zone are indicated, as this may suggest domestication by early rice cultivators in eastern India. Site names abbreviated: *Bk* Bhokardan (Early Historic, 300 BCE–CE 300), *Bg* Bhagimohari (Iron Age, 1000–300 BCE), *Gp* Gopalpur (Late Neolithic, 1500–1200 BCE), *HLR* Hallur (Late Neolithic, 1500–1200 BCE), *PKL* Piklihal (Late Neolithic, 1500–1200 BCE), *PDM* Peddamudiyam (Late Neolithic, 1500–1200 BCE), *SGK* Sanganakallu (Late Neolithic, 1500–1200 BCE), *Tg* Tuljapur Garhi (Chalcolithic, 1500–1200 BCE)

pigeon pea are few and far between in India, "*Cajanus* sp." peas have been identified at Tuljapur Garhi and Sanganakallu in the Deccan Plateau and date to 1500–1000 BCE (Fuller et al. 2004). These sites are situated in an area with no wild populations of *Cajanus*, suggesting that these finds derive from domesticated crop plants. Direct dates for *Cajanus* peas come from Gopalpur and Golbai Sasan, Orissa; the dates of 1400–1300 BCE are the earliest for pigeon pea and come from sedentary settlement sites with established agriculture (Harvey et al. 2006). The natural distribution of the wild progenitor of pigeon pea includes Orissa, suggesting that the pea may have been domesticated there. Pigeon pea appears to be a relatively late domesticate in terms of global agricultural history, at around 1500 BCE. Recent archaeobotanical research in southern Thailand (see Castillo and Fuller 2010) indicates that like other pulses of Indian origin, this species arrived in mainland Southeast Asia, perhaps by sea trade links, before 2,000 years ago (C. Castillo, unpublished data).

Pigeons: Domestication

M. Thomas P. Gilbert[1] and Michael D. Shapiro[2]
[1]Centre for GeoGenetics, University of Copenhagen, Copenhagen, Denmark
[2]Department of Biology, University of Utah, Salt Lake City, UT, USA

Basic Species Information

Domesticated from the rock pigeon (*Columba livia*), the domestic pigeon is an Old World pigeon that, along with over 300 other pigeon and dove species, comprises the family Columbidae, in the order Columbiformes. Although fossil evidence suggests that rock pigeons evolved in Southern Asia, today the natural habitats of the wild rock pigeon are open and semi-open environments across Europe, North Africa, and Western Asia, with a preference for cliffs and rock ledges for breeding. Domestic pigeons, however, and their feral descendants have spread across all permanently inhabited regions of the world.

Pigeons exhibit variations in more traits than any other bird species (Price 2002). Although first domesticated as a source of food, the later spread of the chicken diminished their importance and thus most domestication traits present in modern birds were explicitly selected for exhibition, or to

improve racing speed and homing ability. As a result, the different breeds show dramatic variations in craniofacial structures, color and pattern of plumage pigmentation, feather placement and structure, number and size of axial and appendicular skeletal elements, vocalizations, and flight behaviors (Figs. 1 and 2). This variation is so great that Charles Darwin, the father of modern evolutionary thought, noted that based on morphology alone, a taxonomist might be tempted to classify different breeds as completely different genera (Darwin 1868). Despite their remarkable divergence, pigeon breeds are so obviously unified in their descent from a single ancestral species, that Darwin used them as a key example to illustrate his ground-breaking ideas about natural selection. In particular, he saw pigeons as a striking exemplar of how continual selection can lead to significant, and rapid, morphological and behavioral variations from a single ancestral type (Darwin 1859).

Although pigeons are among the earliest domestic birds and one of the earliest domestic animals (Hansell 1998), relatively little is known about their initial domestication. The rock pigeon today consists of many subspecies spread across Eurasia and North Africa, but exactly which subspecies was the ancestor of domestics, when,

Pigeons: Domestication, Fig. 2 Variations in other traits among domestic pigeon breeds. (**a**, **b**) Extreme beak differences between the Scandaroon (**a**) and Old German owl (**b**) breeds. The Old German owl also has a crest of reversed feathers on the back of its head, a trait present in many domestic breeds but not in the ancestral rock pigeon. (**c**) Fantail breed with supernumerary and elevated tail feathers. (**d**) Cropper breed with a greatly enlarged and inflated crop, an outpocketing of the esophagus. (**e**, **f**) Variation in epidermal structures on the lower hind limb of domestic pigeon breeds. Feathers grow from the skin of the tarsus and foot of some breeds (**e**), while most breeds retain the ancestral trait of scales on the lower limb. (Photo credits: M.D. Shapiro (**a** and **c**-**f**) and S.A. Stringham (**b**))

where, and how many times domestication occurred, and how domestics spread over the majority of their history are largely unknown. Most of the available information comes from written accounts rather than archaeological remains, probably due to both the problem of morphologically discriminating between wild rock pigeons and the earliest ferals and domestic strains, and their relatively fragile bones, which could bias against long-term survival in the archaeological record.

Pigeons are first mentioned in Mesopotamian records over 5,000 years ago, and are documented in most subsequent developed cultures of the region (Johnson and Janiga 1995). The pigeon played a range of important roles in ancient cultures, including messenger, food, pet, religious icon, medicine, and navigation aid. We also know that, in some cultures, the scale of their domestication was immense – ancient Egyptians retained massive populations (as they did with other domesticates such as cats and dogs), sacrificing as many as tens of thousands in single ceremonies. More recently, Akbar of India regularly traveled with a menagerie of thousands of pigeons. As with other domesticated animals (e.g., dogs and cats), interest in fancy breeds increased in the eighteenth century and continues today.

In contrast to the paucity of information about the earliest phase of their domestication, their relatively recent interest to breeders and hobbyists provides historical accounts that help trace the origins of modern breeds. Nevertheless, the diversification of domestic pigeons has received surprisingly little attention from a genetics perspective although recently Stringham et al. (2012) analyzed microsatellites from a broad sample of domestic breeds and found that while it was not possible to recover a well-resolved phylogeny describing the relationships among breeds, pigeons can be loosely subdivided into two ancestral clusters. Furthermore, while pigeons exhibit substantial genetic differentiation at the breed level, a phylogeny was difficult to resolve probably due to the reticular history of many breeds. As with other domesticates such as dogs and chickens, pigeon breeds were (and are) continually hybridized throughout their history in order to modify or add traits. Each of the two ancestral clusters encompasses remarkably different morphologies, with the first principally containing the pouters and croppers, fantails, and mane pigeons, and the second consisting predominantly of the tumblers (the most breed rich group) as well as the owl, wattle, and homing breeds (the latter containing the modern racing homer pigeon, which itself is a hybrid of several ancient breeds).

No discussion of domestic pigeons is complete without mentioning their feral descendants – feral pigeon populations are found in almost all human inhabited locations and, in terms of numbers, represent one of the world's most successful feral animals. In North Africa and Western Asia, feral populations are probably as old as domesticates themselves. The natural homing response of pigeons would have enabled domestics to be released to fly free during the day before returning to man-made lofts, thus providing plenty of opportunity for birds to go feral. The extent of this feralization has been so great, and the opportunities for hybridization between domestic and free-living populations so numerous, that truly wild rock pigeons might be on the verge of genotypic extinction. The chronic genetic contamination of wild populations greatly complicates attempts at resolving exactly when, and where, the original domestication processes occurred. In other regions, the feralization is likely contemporaneous with the introduction of the domestic breeds. For example, pigeons were introduced ~400 years ago in North America by European colonizers. In contrast to the tremendous morphological variations observed among pigeon breeds, the morphology of feral pigeons is remarkably homogenous, with close similarities to racing breeds. Genetic analyses of some feral populations support this association, with feral and racing pigeons being only minimally genetically differentiated (Stringham et al. 2012). This is not surprising given the widespread global interest in racing pigeons, often over long distances and with release from locations unfamiliar to the birds. Racing birds sometimes do not successfully return to their home lofts, and those that survive likely add to the feral pigeon population and gene pool.

Pigment Analysis in Archaeology

Rachel Sarah Popelka-Filcoff
School of Earth Sciences, The University of Melbourne, Melbourne, Victoria, Australia

Introduction

Pigments are a common decorative component found in many archaeological and cultural contexts from around the world. The term "pigment" can be applied to materials that are used to color. Pigment analysis provides data that are valuable in interpreting cultural heritage.

Definition

Pigment analysis has been applied to a variety of materials, including pigments, paints, dyes, and inks. The color properties can arise from either inorganic (mineral pigments) or organic (dyes) materials or, in some cases, a combination of both. Depending on the chemical composition of the pigment and its binder, a variety of destructive and nondestructive techniques can be used to analyze the pigment.

Key Issues/Current Debates/Future Directions/Examples

The analysis of pigment materials has provided an important venue for understanding the cultural heritage as well as the technical qualities of the material itself. Pigments are found in rock art, frescoes, fabric, ceramic slips, manuscripts, body decoration, and virtually the majority of cultural heritage material categories.

Pigment analysis allows insights into the material composition of pigments, which facilitates a more comprehensive understanding of pigment technologies and application processes. In addition, chemical analysis provides insights into the origins of the original source materials. The statistical analysis of samples from sources and objects can provide information on the cultural exchange of pigment materials. In both cases, the appropriate analytical method must be chosen in terms of both the limitations of the technology as well as the potentially destructive effects to the cultural material. For example, a mass spectrometry study of organic components would not be appropriate to analyze the inorganic compounds in pigments. In addition, the resulting data must be interpreted carefully for both cultural context and scientific value. This entry covers some methods most commonly encountered in the literature; however, there are many more analytical

techniques utilized for pigment analysis, and many authors apply a combination of techniques toward understanding specific cases.

In the most ancient contexts, pigments refer to inorganic minerals that are easy to mine and prepare artwork and cultural application. An example of this from the earliest human societies is ochre (Fe-oxide-based minerals) for rock art pictographs (Henshilwood et al. 2001). As a whole, ochre is used nearly universally by early cultures for a variety of applications from burial contexts to paintings and continues into the present. Other ancient pigments included the uses of charcoal or soot for contrast in artwork using black lines and designs. Later Mediterranean and European cultures added to mineral palettes with the addition of pigments such as cinnabar (HgS) and white lead [$(PbCO_3)_2 \cdot Pb(OH)_2$]. During the Renaissance, such pigments as Naples yellow [$Pb(SbO_3)_2$/ $Pb_3(Sb_3O_4)_2$] and ultramarine ($Na_{8\text{-}10}$-$Al_6Si_6O_{24}S_{2\text{–}4}$) were introduced. In the Americas, Maya blue (a mixture of indigo and palygorskite clay) was used extensively since about 800 A.-D. until the sixteenth century. With various technological advances since the early nineteenth century, new pigments based on cobalt and chromium were developed (such as cobalt blue [$CoAl_2O_4$] and chrome yellow [$PbCrO_4$]). Other organic-based pigments were also derived in the twentieth century, although these and other modern pigments since the nineteenth century are of interest to archaeology and conservation more so for detecting forgeries or for conservation of archaeological examples. An exception to this is Egyptian blue, ($CaCuSi_4O_{10}$), synthesized in ancient Egypt from approximately 2500 BCE to the fourth century CE (Doménech-Carbó et al. 2013).

One of the historic challenges of pigment analysis is the destructive nature of sampling, whether it is physical or chemical. In many cases, the need for further data and information necessitates the destruction of a small amount of pigment sampled by a skilled conservator, and the data obtained outweighs the insignificant damage to the object. In other cases, sampling is not possible for a variety of reasons, and analysis is limited only to nondestructive techniques. In the majority of cases, if nondestructive techniques are available and provide the same quality or quantity of data, these methods are preferred, but they are not always applicable due to the complexity of the object. For such techniques as neutron activation analysis (NAA), or various forms of mass spectrometry (MS), a small sample on the order of milligrams is required, whereas techniques such as Raman spectroscopy are generally nondestructive provided that the object can fit into the instrumentation. Recent technology in spectroscopic techniques such as Raman and IR spectroscopy has allowed portable instrumentation with fiber-optic probes that can provide data on pigment composition without contact with the object. Many museums and archaeological expeditions also have been using handheld portable X-ray (PXRF) instrumentation that provides qualitative information on elemental composition of the pigments and substrate, depending on the thickness and composition of the pigment (Frahm and Doonan 2013). Quantitative analysis of pigments by portable instrumentation is often hindered by surface effects and nonuniform coverage of pigments, as well as the shape of the original object. Under controlled conditions, these effects can be minimized for quantitative analyses.

Raman spectroscopy has found significant advantage in pigment identification due to its nondestructive qualities, while also providing reproducible data with high sensitivity. Given the appropriate equipment, the analyses can also be performed in situ, which is a significant advantage in the museum or archaeological site context. The authors L. Burgio and R.J.H. Clark have published significantly in this area, primarily on European works, but also on objects from stuccos, papyri pigments, and Asian manuscripts. The authors have also compiled a comprehensive database of spectra of FT-Raman spectra of interest to cultural heritage (Burgio and Clark 2001). Edwards et al. recently published a book on the applications of Raman spectroscopy to archaeological contexts, including several chapters that were concerned with pigment applications (Edwards and Jaan 2009).

As mentioned earlier, XRF (X-ray fluorescence spectroscopy) instrumentation has been

used increasingly worldwide for the elemental identification of pigments. The majority of applications are of PXRF (portable X-ray fluorescence spectroscopy) through the use of a battery-operated handheld instrument. Bonizzoni et al. recently completed a study to evaluate the advantages and limitations of investigating pigment layering using PXRF and UV-visible spectroscopy (Bonizzoni et al. 2008). This study determined that a combination of methods was effective for the identification of two layers, but in examples with more than one layer, qualitative data could be used on elemental identification. Another recent study investigated Hellenistic plasters by PXRF, among other methods (Aquilia et al. 2012). A recent manuscript reviews the applications of PXRF to archaeology in the literature, including pigment applications (Frahm and Doonan 2013). X-ray fluorescence spectroscopy has also found use in archaeological materials, with the capabilities to measure spot sizes down to 5 μ. While requiring a synchrotron facility, this capability allows elemental mapping and quantification of pigment composition which cannot be achieved with the larger spot sizes of lab-based instrumentation (Popelka-Filcoff et al. 2016; Bergmann et al. 2012).

While the majority of studies on pigments have investigated composition, some recent works have also studied pigments as indicators of cultural exchange in a similar manner to materials such as obsidian and ceramics. These studies are based around the framework that trace compositions of the materials are indicators of the origins of the pigment materials. Duwe and Neff use laser ablation inductively coupled mass spectrometry (LA-ICP-MS) to investigate the recipes and exchange of paints on Pueblo ceramics from Arizona (Duwe and Neff 2007). Popelka-Filcoff and Eiselt et al. have also applied this concept to the provenance of ochre pigments in North America and Australia (Eiselt et al. 2011; Popelka-Filcoff et al. 2012).

In addition to the identification of pigment components, the identification of the pigment binder has also proven useful in archaeological studies. Binders often contain additional information on the pigment application technique as well as information on cultural trends. Separation techniques for the identification of binders include varying forms of gas chromatography as the most common technique (Bocchini and Traldi 1998; Casoli et al. 1996). As with other analytical studies, methodologies from other fields have been adapted for cultural heritage use as in the use of immunodetection of proteins in binders (Cartechini et al. 2010).

While the identification of pigments often reveals information on the pigment composition, other techniques can provide data on the age of the pigments. In the case of prehistoric pigments made of soot (carbon based), in some cases, the carbon in the pigment can be dated. Originally developed at Texas A&M University, this technique uses sub-milligram quantities of carbon to date rock art. An example of this work is the dating of rock art from Guatemala (Armitage et al. 2001).

In addition to methods that are relatively well established in the literature, new methodologies from analytical chemistry are finding applications in pigment analysis. A recent example of methodologies adapted from nanotechnology is SERS (surface-enhanced Raman spectroscopy), where the technique realizes enhanced Raman signal through the application of molecules on the pigment surface. A recent study by Brosseau et al. demonstrates use of the direct, non-extraction, technique on artist media. Casadio et al. describe the application of SERS to organic dyes from several cultural applications (Casadio et al. 2010). In addition, varying types of mass spectrometry have demonstrated use in pigment analysis. For example, DeRoo and Armitage recently published a manuscript on the use of DART (direct analysis in real time) mass spectrometry for organic dye compounds (Selvius DeRoo and Armitage 2011). While several established and commercially available methods are used routinely in laboratories and museums worldwide, the literature has many examples of adapting non-conventional analytical methods to understand pigments (e.g., voltammetry and electrochemical microscopy, among others) (Doménech-Carbó et al. 2013).

Pigment analysis by a variety of methods provides data and cultural interpretations of materials

from the inorganic, organic, and binder components of pigments from a variety of cultures and applications. While new technologies offer innovative ways to investigate pigments, care must be taken in the application of these methods and in the subsequent interpretation of data and cultural analysis in order to produce a meaningful archaeological science study.

Pikirayi, Innocent (Historical Archaeology)

Natalie Swanepoel
University of South Africa, Pretoria, South Africa

Basic Biographical Information

Professor Innocent Pikirayi was born in 1963 in Masvingo, Zimbabwe. He obtained a BA (honors) degree in history (1985) and an MA in African history (1987) from the University of Zimbabwe, where he received training from archaeologists such as Peter Garlake and Robert Soper. He combined his interests in history and archaeology in further studies, receiving his Ph. D. in historical archaeology from the University of Uppsala where his dissertation was entitled *The Archaeological Identity of the Mutapa State: Towards an Historical Archaeology of Northern Zimbabwe* (Pikirayi 1994). Pikirayi began his teaching career in archaeology at the University of Zimbabwe in 1988, attaining the rank of senior lecturer in archaeology in 2001. In 2004 he joined the staff of Midlands State University (Zimbabwe) as senior lecturer in archaeology and executive dean of the Faculty of Arts. In 2005 he relocated to South Africa to work at the University of Pretoria where, in May 2010, he became a full professor of archaeology and head of department of the Anthropology and Archaeology Department (Pikirayi pers. comm.).

Major Accomplishments

Pikirayi has made a substantive contribution to the archaeology of the southern African later Iron Age, especially to the archaeology of the Great Zimbabwe period (c. 1290–1450) and the post-Great Zimbabwe or Khami-era (c. 1450–1835). Theoretically, his interest has been in furthering understanding of how sociopolitical complexity originated, developed, and eventually declined at the site of Great Zimbabwe and its surrounds. Pikirayi has published extensively on this both singly (Pikirayi 2001) and in tandem with other Zimbabwean scholars, including a prizewinning *Antiquity* article in 2008 (Chirikure and Pikirayi 2008). More recently, he has turned his attention to Mapungubwe and other archaic states in southern Africa and the factors that may have led to their rise and demise (Pikirayi 2017). The study of the regional and spatial contexts of these states, including Great Zimbabwe and Mapungubwe, forms part of his participation in the larger "Urban Mind" project, led by scholars based at the University of Uppsala (Pikirayi pers. comm.).

Pikirayi has long been interested in exploring different aspects of public archaeology and the relevance of archaeology and heritage in post-colonial Africa. His participation in the University of Pretoria Mapungubwe Committee, tasked with the repatriation and restitution of cultural and skeletal remains from the site of Mapungubwe,

led him to further consider the role of public archaeology and the relevance of archaeological practice to descendant communities in South Africa and to publish his book *Tradition, Archaeological Heritage Protection and Communities in the Limpopo Province of South Africa* in 2011. He has strongly advocated for the need to decolonize the discipline of archaeology within the African continent by developing theories and practices relevant to and emanating from the local African context (Pikirayi 2015).

He has advanced the field of historical archaeology in the southern African subcontinent in his historical archaeological investigation of the Mutapa State (1450–1900). This work was important not only for yielding valuable data about the post-Great Zimbabwe period but also for increasing academic understanding of African-European interactions, colonialism, and conflict. In particular, he used archaeological data to contest written Portuguese accounts of the political status quo in the Mutapa State (Pikirayi 2009). Pikirayi is a specialist in the analysis of archaeological ceramics and has conducted ethno-archaeological research on pottery production, distribution, and use in Swaziland and eastern and northern South Africa and has written on the relationships between group identity and ceramics (Pikirayi 2007).

He has played an important role in furthering cultural heritage management in Zimbabwe serving as vice-president of the International Council on Monuments and Sites (ICOMOS), Zimbabwe, from 1997 to 2003 and as president from 2003 to 2004. During that time he headed up the ICOMOS-Zimbabwe evaluation mission for the nomination of the Matobo Hills to the World Heritage List (Pikirayi pers. comm.).

Pikirayi, Innocent (Indigenous Archaeology)

Ashton Sinamai
School of Humanities and Social Sciences,
Deakin University, Melbourne, VIC, Australia

Basic Biographical Information

Born in 1963, Innocent Pikirayi grew up in Zimuto, a district in Masvingo (formerly Victoria) Province of Zimbabwe (Fig. 1). His father was a carpenter in the Public Works Department in the then Rhodesia from which he resigned following the intensification of the liberation war in the late 1970s. His mother was a stay-at-home mum who engaged in subsistence farming and largely saw the children through to school. A practicing Catholic, Innocent Pikirayi is married to Susan Philistus Muzivi, and they have two daughters and a son. The fifth born in a family of seven, he attended local schools run by missionaries and later a multiracial school in the same province before heading for the University of Zimbabwe (UZ) for his undergraduate studies where he developed an interest in archaeology.

Pikirayi, Innocent (Indigenous Archaeology), Fig. 1 Innocent Pikirayi

Innocent entered university in 1983, just after Zimbabwe's independence. Many archaeologists who had worked in Zimbabwe had left after the fall of a Rhodesian government that had declared unilateral independence from the United Kingdom in 1965. There was therefore an urgent need to train indigenous archaeologists who would "correct" the biased archaeology that had developed under a nationalist settler government. He is therefore one of the first indigenous Zimbabweans to receive training in Archaeology.

His encounter with archaeology was at 2nd year level at university (1984), where he had already enrolled as an honors student in history. Two people influenced his decision to take up archaeology: Professor Vella, a classicist from Malta, and Dr. Peter Garlake, whose presence at UZ in 1983 and 1984 is instrumental in his decision to take up archaeology as a career. The subsequent arrival of Robert Soper and Gilbert Pwiti at UZ, the introduction of archaeology as a degree, and the SIDA-SAREC-funded research project *Urban Origins in Eastern and Southern Africa* (coordinated by Uppsala University and the Swedish National Board of Antiquities) saw Innocent Pikirayi embarking on Ph.D. studies in 1988. His doctoral thesis was shaped by this project and resulted in a monograph on the historical archaeology Mutapa State (CE 1450–1900) in northern Zimbabwe. Paul Sinclair from Uppsala University was Innocent's supervisor and mentor for his Ph. D., which was completed in 1992. Since then, he has embarked on a program of research and publication, focusing on the origins, development and decline of state societies on the Zimbabwe plateau, the development of African ceramic traditions during the last 2000 years, as well as archaeology in contemporary politics and society.

Currently, Innocent Pikirayi holds the position of Chair in the Department of Anthropology and Professor in Archaeology at the University of Pretoria, South Africa. In 2009, he was appointed Docent in Archaeology by the Department of Archaeology and Ancient History at Uppsala University. Previously he has worked as a Dean and Senior Lecturer in Archaeology in the Faculty of

Arts at Midlands State University in Zimbabwe. He has also worked as Lecturer and Senior Lecturer at the University of Zimbabwe. In 2000 he was a Visiting Commonwealth Fellow and Scholar at the Pitt Rivers Museum, Oxford University.

He has mentored many of the second-generation indigenous archaeologists who have worked and continue to work for the National Museums and Monuments of Zimbabwe (NMMZ) and the two universities teaching archaeology in Zimbabwe, viz, the University of Zimbabwe and Midlands State University. He has worked closely with NMMZ in the development of management plans for Zimbabwe's World Heritage Sites and played a huge role in the organization of the ICOMOS 14th General Assembly and Scientific Symposium which was held in Victoria Falls in 2003. A jovial character who is always happy to assist peers and students, Professor Pikirayi is highly respected in archaeology circles in his native Zimbabwe, Africa, and the world.

Major Accomplishments

Professor Pikirayi's research interests are in the late farming communities of southern Africa. He has published widely and consistently on the Zimbabwe culture as well as on ceramic traditions of southern Africa for the past 25 years. Professor Pikirayi has written and edited books and articles on the rise, development, and decline of the Zimbabwe culture. His major scientific contribution however has been in ceramic studies, and his in that area has illuminated the prehistory of Zimbabwe and southern Africa. Currently, Professor Pikirayi is researching on archaeological and ethnographic ceramics in southern Africa, examining issues in the production, distribution, use, and relationships between ceramic remains and group identity. He has also developed an interest in public archaeology especially in understanding how indigenous communities can participate and engage with Archaeology as well as conservation of archaeological sites.

Innocent Pikirayi has contributed tremendously to the understanding of the second millennium in Zimbabwe and adjacent regions. His book, *The Zimbabwe Culture* (Pikirayi 2001) has become one of the most important texts for students studying later farming communities and complex societies of southern Africa. This book combined oral traditions, archaeology, and archival documents to produce a synthesis of the history of Zimbabwe and adjacent areas in the second millennium. The book analyzed new evidence on the origin, development, and decline of an extraordinary culture, the Zimbabwe culture (1050–1850). It also discusses the early Zimbabwe phase of Mapungubwe and shows how it contributed to the development the Great Zimbabwe and Khami phases. *The Zimbabwe Culture* discusses the later periods in which the latter states had contacts with the Portuguese as well as the colonial interface with the British and other European countries. One of his recent articles (in collaboration with one of his former student, Shadreck Chirikure) on the use of space at Great Zimbabwe was published by Antiquity in 2009 and was judged the best article for the year by the same journal (Chirikure and Pikirayi 2008). Professor Pikirayi has served as a reviewer and advisor for the National Research Foundation, South Africa, and is also an editorial board member for *Azania:* the *Journal of African Archaeological Research* and the *African Archaeological Review*. He was also editorial advisor for the *Encyclopedia of Precolonial Africa: Archaeology, History, Language, Cultures, and Environments* published by Altamira Press in 1997 and reviewer of the UNESCO General History of Africa volumes which were published in 2010.

Pilar Luna Erreguerena

Rosa María Roffiel
Subdirección de Arqueología Subacuática,
Instituto Nacional de Antropología e Historia,
Mexico City, Mexico

Basic Biographical Information

Pilar Luna Erreguerena (1944) was born in the port of Tampico, in the state of Tamaulipas, México. In 1982, she obtained her Bachelor in Archaeology at the National School of Anthropology and History (ENAH) and her Master in Anthropological Sciences at the National Autonomous University of Mexico (UNAM). She was in charge of Section 3 of the important diggings of the Aztec Main Temple, downtown Mexico City, where in 1978 she discovered the famous pink stone shell sculpture exhibited now at this site museum. This was her last work as a land archaeologist. Since she was a student she had wondered about the cultural heritage underwater. Searching at the National Museum of Anthropology's library, she found only one book regarding this topic, authored by Dr. George F. Bass – considered as "the father of underwater archaeology." In 1979 she invited him to impart the core of the first underwater archaeology course ever given in Mexico, at the end of which, Dr. Bass invited her to Turkey to participate in the last field season of the excavation of a 1025 Byzantine shipwreck known as the Glass Wreck. In February 1980, after a long struggle headed by Luna Erreguerena, the National Institute of Anthropology and History (INAH) created an underwater archaeology division (Luna 2002:272). She was appointed as head of that area, where she served for more than 37 years, until April 2017 when she semi-retired to be dedicated mainly to the *Underwater Archaeological Project Hoyo Negro, Tulum, Quintana Roo*, which in December 2017 received the SAF (Shanghai Archaeological Forum) Field Discovery Award, given by the Institute of Archaeology at the Chinese Academy of Social Sciences, for the finding of the most complete skeleton ever recovered in the Americas, belonging to a female who was between 15 and 17 years old and lived in the Yucatan Peninsula between 13,000 and 12,000 cal BP, as well as an important deposit of extinct megafauna (Chatters et al. 2014:753). In 2014, the discovery of the human skeleton, known as Naia, was considered among the ten most important ones in the world by the North American magazines *Discover* and *Archaeology*.

Major Accomplishments

Pilar Luna is considered the pioneer of underwater archaeology in Mexico and has supported this discipline in other Latin American countries. Since the beginning, her priorities always were the training of underwater archaeologists and the development of projects both in marine and

Pilar Luna Erreguerena, Fig. 1 Pilar Luna facing the sea in Veracruz. (Credit: Canal Once México)

continental waters with a multidisciplinary, multi-institutional, and international approach. The generous support of colleagues, mainly from the United States and Canada, has been vital in the unfoldment of Mexican underwater archaeology. She is also recognized for her strong position defending Mexico's underwater cultural legacy against treasure hunters and played an important role in the elaboration of the 2001 UNESCO Convention on the Protection of the Underwater Cultural Heritage (Luna Erreguerena 2011a:985). In 2010 she coordinated the course "Underwater and Maritime Archaeology Research and Management," organized by INAH and UNESCO: 27 students from 14 countries of Latin America and the Caribbean participated (Luna Erreguerena 2011b:34). Archaeologist Pilar Luna Erreguerena has received national and international recognitions such as the Award of Merit "for pioneering in the recognition, exploration and preservation of the underwater archaeological heritage of Mexico" in 1997 and the J.C. Harrington Medal "for Her Lifetime Contributions and Dedication to Historical and Underwater Archaeology" in 2011, both presented by the Society for Historical Archaeology (SHA). She was the first Latin American woman and the second underwater archaeologist, after Dr. Bass, to receive this medal. The most recent recognition was the Investigation Award given by the Spanish Geographic Society in 2016 in Madrid. She is one of the best known and respected figures in underwater archaeology in the world. However, her major accomplishment is the nobility and kindness of her heart and the delicacy and respect to treat others (Figs. 1 and 2).

P

Pile Dwellings or Stilt Houses in Prehistory of Brazil

Alexandre Guida Navarro
Laboratory of Archaeology, Department of History, Federal University of Maranhão, São Luís, Brazil

Introduction

Around the 1950s, an American archaeologist, Betty J. Meggers, penetrated the Amazonian tropical forest, together with her husband, Clifford

Evans, placing the Amazon in the spotlights of South American Archaeology (Meggers 1954). Due to their orientations in ecological determinism, the researchers in question explained that the known vestiges of complex societies are derived from peoples coming from the Andes. Their argument was that the acid ground of the Amazonian region, created by abundant rains, removed the minerals, disabling, this way, the success of agriculture that, at that time, was considered the main cultural factor in civilization development (Meggers and Evans 1957). In this interpretation, it was impossible that a civilization could have developed in this inhospitable environment. The Amazon was, therefore, the illusion of a paradise, an epithet that even became the title of one of Betty Meggers' books (1987).

In the 1960s, the Evans couple led the PRONAPA (National Program of Archaeological Research) in Brazil, with other Brazilian and foreign archaeologists as Hilbert (1962) and Simões (1981), who corroborated in the studies using the archaeological record of Central Amazon to create a typology that found an allochthonous origin, external to the human groups in precolonial Amazon. Also other American and Brazilian researchers saw these same records as evidence of processes of local social transformation (Lathrap 1970; Brochado 1984).

However, at the beginning of the 1980s, archaeologist Anna C. Roosevelt internationalized the archaeological research in Amazon (Roosevelt 1980, 1989). From the experience acquired in the region of the Orinoco River, Venezuela, this researcher demonstrated, mainly in her excavations in Marajo Island, that the societies that had established in the estuary of the Amazon River, as well as those that settled along the margins, and up the river, were of local origin (Roosevelt 1991). Although the Amazonian high ground really is barren, it has many alluvial floodplains, and also there is a man-made soil known as black earth; it was in these types of earth that such Amazonian societies gained much of their economic sustenance. In this sense, the Amazonian societies developed from the culture of maize and others crops (corn) in these anthropocentric lands, and this would explain the emergence of complex societies in the Amazonian basin. The Indians lived in large settlements that were linked to cultural and political territories ruled by overlords they believed were was of divine origin. They developed complex earthworks, by modifying the environment, as the mound buildings in Marajo Island; they were sometimes bellicose and expansionist societies (Roosevelt 1991). In this way, the basin Amazon's studies by Roosevelt was corroborated by subsequent fieldwork (Porro 1992; Balée 1994; Denevan 2001; Schaan 2004; Petersen et al. 2003; Heckenberger 2005; Hornborg 2005; Neves 2008; Rostain 2010; Gomes 2012).

The project we develop is placed in the context of the theoretical discussions concerning the development of past societies in the lowlands of South America, in this case, the Brazilian Amazon. The project has 4 years to be developed (2015–2018). In this article, we present the preliminary results from 2 years of research. If nowadays there is a reasonable knowledge about the cultural picture of precolonial Amazonian societies, on the other hand, very little is known about an important type of human settlement in the southeast of this region, where these sites are located.

What Are Pile Dwellings?

The region where the pile dwellings (estearias) occur is the Maranhão's state in northwest of Brazil (Baixada Maranhense) (Figs. 1 and 2). It is a microregion situated to the west and southeast of the island of Maranhão; it comprises an area of approximately 20,000 km^2 inside of Legal Amazon, a region that contains more than 500,000 inhabitants (census IBGE 2006). It is a very poor territory, with the lowest HDI not only of the State of Maranhão but of all Brazil, whose population lives out of the subsistence of traditional agriculture, fishing, raising of small animals, and vegetal extractivism, especially of the babaçu coconut. The main cities of this area are Penalva, Pinheiro, Viana, and Santa Helena (Navarro 2014, 2016). We are studying the sites located in Santa Helena city on the Turiaçu River.

Pile Dwellings or Stilt Houses in Prehistory of Brazil, Fig 1 Maps of the pile dwellings' localization

The pile dwellings were lacustrine housings constructed with wooden pillars (stumps or trunks of trees) which served as sustentation for the superior constructions, originating, thus, its villages or the prehistoric palafittes (Raimundo Lopes 1916; Correia Lima and Lima Aroso 1989;

P

Pile Dwellings or Stilt Houses in Prehistory of Brazil, Fig. 2 Maps of the pile dwellings' localization

Leite Filho 2010) (Fig. 3). This type of archaeological site appears in isolated cases in South America, as in Vespucius' stories of 1499 about communities that lived in palafittes in the Venezuelan coast. However, pile dwelling sites existing in many places, including Marajo, today, may have been more common in prehistoric times.

In Brazil, several authors consider that the pile dwellings are the least known archaeological sites in the national territory (Prous 1992; Martin 1996). Even though reports by palafitte dwellers in the upper Amazon River described by the expeditions of Ursúa and Aguirre (1516) and Porro (1992) and of stories by Frenchmen from the seventeenth century of communities living in palafittes in regions that correspond to where the States of Para and Maranhão are today (D'Abbeville 2008 [1614]; D'Evreux 2008 [1615]; João Daniel 2004 [1757–1776]), the pile dwellings of Maranhão are the only ones with known material vestiges in the present time. The main importance of studying these sites is their favorable preservation condition. The aquatic environment preserved them in an unparalleled way, in such a way that the paintings on the artifacts, as well as the material made of wood and even the hut's straw, are well conserved.

The pile dwellings are located throughout the diverse lakes that are characterized by the formation of a water system composed of rivers, flooding fields, and lakes of various sizes that are defined by the seasonality of the climate (floodings occur in the first semester of each year) (Franco 2012). The lakes of Maranhão lowlands have recent geological origin, Pleistocene, and are characterized by periodic floodings in the rainy season, because they end up receiving pluvial waters and receiving, in addition, the waters of the rivers in the region when they overflow, such as the Pindaré, Pericumã, and Turiaçu (Corrêa et al. 1991; Ab' Sáber 2006). They belong, also, to a typical biome of the Amazonic region which is characterized by fertile valley fields.

Pile Dwellings or Stilt Houses in Prehistory of Brazil, Fig. 3 The pile dwellings in the dry season

Current archaeological research carried through in the Amazon region demonstrates that the fertile valleys of the rivers in the region were densely populated by societies of the chiefdom type in Amazonian prehistory (Roosevelt 1980; Heckenberger 2005; Neves 2008). We can affirm, in hypothetical level, that, in principle, the existence of abundant feeding in these lakes could favor sedentary habitation of the human groups that occupied the region.

Although it is still very incipient to infer the type of social organization of the pile dwellings, it is important to highlight that the aquatic biome and the ideal conditions of food attainment are similar to the ones in the Amazonian fertile valleys, which makes us infer that this rich environment was paramount to the development of the palafitte dwelling societies. The evidence of this adaptation is supplied by the description by Simões (1981) who measured one of the pile dwellings and could delimit its area to 2 km, therefore a site of considerable dimensions.

On the other hand, he still does not answer who were these lacustrine communities. For Raimundo Lopes (1916), they are delayed populations of Amazonian filiation that are migrating into the lowland region. For Correia Lima and Lima Aroso (1989) they are Arawak groups that have been expelled, later, by the Tupiguarani occupation. For Leite Filho (2010: 255), the estearias were formed by "intrusive groups in the region that organized themselves in independent villages or inversely in a set of habitations with some political bond among them, given their cultural homogeneity and contemporaneity."

Discussion

Ethnohistorical reports of the sixteenth century AD, mainly by the priests Claude D' Abbeville, D'Evreux, and João Daniel, are an important information corpus concerning the Indians who inhabited Maranhão in the period of the Conquest. However, the majority of reports narrate the Tupi-Guarani occupation in the island of São Luís. These historical documents narrate several aspects of aboriginal daily life, as space organization, war, and the way they fed (Porro 1992).

With regard to the pile dwellings of the lowlands, there are no reports of the construction of palafittes in precolonial Maranhão, but there are mentions in the region of where is the State Pará today and in the Highlands, Amazon region. The best example of these reports the expedition of Ursúa and Aguirre in the High Amazon when they got in touch with the Omágua, aboriginal group

Pile Dwellings or Stilt Houses in Prehistory of Brazil, Fig. 4 The mapping poles were carried through with total station and satellite georeferencing (GPS and GIS)

that lived in palafittes, indicating that these lacustrine housings could have been fortified:

> We went down the river for five or six days (...) *We arrived at some strong houses that the Indians have there, made of jirau, high and surrounded by boards of palm tree and (that) have, up in the building, small windows for shooting arrows, and from up there, the Indians wounded four of five Spaniards*, with twenty that had themselves in advance with a chief, and had made them withdraw; when the armada arrived at this house the Indians had run away… When we wanted to leave this place, appeared in the river many canoes and Indians, which, according to some, could be more than 100, with many Indians of war. (Porro 1992: 95)

In the eighteenth century AD, the Jesuit João Daniel wrote the following on the palafitte dwelling peoples of the Amazon, inferring a possible meaning of these types of constructions:

> Many nations live on lakes, or among them, where they have, over the water, their houses made of the same sort, only with the amend of being out of hay, that they erect with poles, and palm tree branches, and in them they live joyfully, like fish in the water. One reason they manufacture in the lakes their populations and housings is the great abundance of turtles, marine oxen, and more fish in them, other reason is for them to be safe from their enemies' assaults. (Daniel 2004: 280)

So far, our team mapped the archaeological sites of Armindio, Caboclo, Encantado, and Boca do Rio. The mapping was carried through with total station and satellite georeferencing (GPS and GIS). Considering that the riverbeds go through a strong silting process, besides the fact that the sand forms a layer on the poles, hindering their identification, the most adequate method was the following: through rafts, we identified each pole manually and marked them, locating, this way, the delimitation of the sites as well as the majority of the poles that could be referenced by the total station. We must take into consideration, on the other hand, that this method also has margin for imperfection, given that some poles may have been left unseen by one of the team members. However, it is considered that the highest number of poles was mapped satisfactorily, once that the form of the villages was visibly identified (Fig. 4).

Eloquent results were obtained. The biggest mapped site is Encantado, with an extension of 13 ha and 171 visible poles, being that, according to locals, a third of the poles were destroyed for attainment of the wood used in local activities, as the erection of fences. On the other hand, the Boca do Rio site, of only 1 ha, presented the highest number of poles: a total of 1100 (Figs. 5 and 6).

Given the subaqueous nature of the sites, systematic collections were also performed in the drought season, when fluvial deposits lower their

Pile Dwellings or Stilt Houses in Prehistory of Brazil, Fig 5 The Boca do Rio site, of only 1 ha, presented the highest number of poles: a total of 1100

level (50 cm of water), but do not dry out, a situation that led to the collections. This way, the sites were divided on a Cartesian plane with randomly selected points of 1 × 1 and, from this, the superficial archaeological materials correspondent to each one of these points were removed. Among the several collected materials, both entire and broken ceramic artifacts are found, being painted and not painted: many figurines; lithic material and wooden pieces, as the helve of an axe; spindle stems; and supposedly one oar (and/or borduna?).

Regarding chronology, six radiocarbon dates from woods have been carried through for the sites, as can be observed on the table below (the dates are calibrated) (Table 1). The majority of the sites are contemporary, and the fact that they were constructed between the eighth and tenth centuries correspond to complex relation of societies that occupied the Amazon in the precolonial period, establishing direct and indirect contact with them.

Spatial analysis evidences elliptical or circular villages built in the center of the rivers or lakes, whose function is still unknown, but it possibly has to do with the attainment of food or for defense purposes. There is an architectural construction hierarchy, where the highest amount of poles is located in the central part of the villages, and, further from the center, there is a gradual reduction of wooden sticks, until they disappear. This hierarchy also promotes the concentration of groups of poles in different places of the sites, which may mean that they had been linked by bridges (Willey and Philips 1958; Shanks and Tilley 1987; Hodder 1994; Ucko 1995). Spatial

associations with anthropo-zoomorphic figurines, one of whose main characteristics is the representation of the navel, evidence a magical-religious character for some sites that are located precisely in the center of the lakes or rivers. The association of the figurines' navels with the spatial localization of the village in the center of the rivers could be symbolic evidence of hierarchic societies that saw themselves as axis mundi, that is, that they were located in the center of the universe (Sahlins 1968; Reichel-Dolmatoff 1971; Geertz 1973; Roe 1982; Renfrew 1986; Earle 1990; Vidal 1992; Velthem 1992; Gell 1998; Lagrou 2007).

Corroborating these data, ceramic statuettes from the sites indicate the presence of ritual in these palafitte dwelling societies. They are characterized by representation of animals, mainly the owl, the monkey, the turtle, and the frog (Fig. 7). Some of them are anthropo-zoomorphic, being the zoomorph form most recurrent. The majority of them follow a sculptory standard: the legs are

open forming a half-moon shape, and some of them have the feminine genitalia exposed. The profusion of the feminine statuettes with the female genitalia may be evidence of some sort of ritual associated with fertility or puberty, mainly because many of them show evidence of having had their heads broken (Schaan 2004; Barreto 2008; Gomes 2012) (Fig. 8).

Pile Dwellings or Stilt Houses in Prehistory of Brazil, Fig. 7 Owl anthropo-zoomorphic figure

One of them, especially, evokes the question of the Amerindian perspectivism (Viveiros de Castro 2002) in the art of these peoples: in lying position, it is a frog; standing, it is an owl with a human trunk, in addition to the arms, also human. Almost all of them feature another important trace: the designing of the navel that, as told previously, is associated with the way these societies see the world (Eliade 1969). The spindles, discs in ceramic with punctures, are also an important type of device found in the pile dwellings, and in different sizes, and indicate the activity of weaving (Fig. 9).

The ceramic artifacts were classified according to a typology that obeyed the following categories: flat form (plate), vessels of the half-calotte type, spherical vessels with appliqués, hemispheric vessels, figurines, and spindles. A characteristic of the collection is the presence of small ceramic vessels that probably served for storing very controlled amounts of liquid in its interior or seeds for plantation, as indicated by Burke et al. (1971). Some of them have incisions on the edges; others are painted, normally of red and black, without the presence of engobe. The plates are plane utensils, and they present marks of straw mats, being the tressed pattern the most frequent.

Pile Dwellings or Stilt Houses in Prehistory of Brazil, Fig. 8 Feminine statuette or figurine with the genitalia

Pile Dwellings or Stilt Houses in Prehistory of Brazil, Fig. 9 A frog-man figurine evokes the question of the Amerindian perspectivism

The main manufacture techniques observed in the vessels are coiling and molding. As far as the antiplastic, cauixi predominates (a fresh water sponge), appearing, also, grog, minerals (in special quartz grains), coal, sometimes, caraipé (tree bark ashes). The appliques, glued to the side of the vessels, are another diagnostic characteristic of the pile dwellings devices. In general, they are breast-shaped, and sometimes, zoomorphic. Other devices that appear less frequently are vessels with handles and vases with necks.

With regard to the iconography, it is highlighted the geometric traces in the stylistic composition of the vase: they are grecas or spiral lines that surround the interior of the parts. The predominant colors are red and black. Probably, many feature drawings of motifs that represent the animal skins, as on a sample, in which we can notice the marks of the turtle carapace or the skin of a surucucu snake *(Lachesis muta)*, which was common in the region of Maranhão lowlands.

The most important discovery of the research is the *muiraquitã* representing a frog (Fig. 10).

Pile Dwellings or Stilt Houses in Prehistory of Brazil, Fig. 10 The green stone nephrite muiraquitã

The piece of green stone (nephrite), which was found in the pile dwellings of Boca do Rio, is the first such artifact collected in a systematic way, except at Santarem, since the findings of Raimundo Lopes, 100 years ago. The mineralogical analysis was carried through by Pará Federal

University, evidencing that the specimen is of green nephrite, confectioned from the minerals tremolite/actinolite. The piece is 2.8 cm in height by 1.8 cm in length, having two lateral punctures and marks of the retouching of the chipping and burnishing on the back. As far as style, it is hybrid, because the abdomen and paws are identical to traditional Amazonian *muiraquitãs*, mainly to the ones from Santarem on the Tapajos River. However, the bipartite head sometimes resembles Caribbean traces (Venezuela, Guianas, and Caribbean Islands) and sometimes resembles the symmetries of Andean South America (the quadrangular eyes), such as the Tolima culture of Colombia (Boomert 1987; Rodríguez Ramos 2013).

Ornaments in green stone are also characteristic of the Isthmus-Antilles region, suggesting that the connections between the Mesoamerica and the Caribbean were much more active than what Kirchhoff imagined when considering different cultural areas for distinct geographic regions (Kirchhoff 1960; Boomert 1987; Domínguez and Funari 2012). Recent archaeological discoveries in Amazonia of bird-shaped pendants (as the condor, typical Andean bird) and images of reptiles and batrachians adornments, show evident interaction among the human groups that inhabited the Antilles and the region of Colombia, covering an area that extends from the northwest of Venezuela to the occidental portion of the Honduras.

In the highlands and lowlands of South America, this type of archaeological material, even though commonly found, still is little studied. Rostain (2010) associates the manufacture of *muiraquitãs* to an activity of specialization directed toward the long-distance commerce in societies of the chiefdom type. This researcher relates the production of green rock with a complex system of interchange between Arauquinoid societies that inhabited the mounds typical of the coasts of Guiana. Since rocky outcropping is rare in this region, mainly in the coast, the green rocks were probably imported from somewhere else.

Conclusion

The pile dwellings (estearias) or palafitte sites are a unique type of archaeological site in the context of Brazilian prehistory. These sites possess abundant and well-preserved objects. Little were they studied, and they did not receive the due attention on the part of the archaeologists, mainly due to absence of systematic research in Maranhão. The Laboratory of Archaeology of the Federal University of Maranhão (LARQ/UFMA) comes to fill up this gap.

For being well conserved, in aquatic environment, they are an important certification of the societies that inhabited this Amazonian region. The analysis carried out until the moment evidences the research potentiality of these sites. In them it is possible to find paleobotanical (remaining portions of seeds), architectural (pile dwellings arrangement), ceramic (with complex geometric motifs), and lithic (as the axes) vestiges.

The analysis of the ethnohistorical sources evidenced scarce information concerning these populations, revealing that these groups are considerably old, in such a way that, to the time of the Conquest, the Indians did not preserve in their memories stories concerning these societies. It is very likely that the aboriginal groups of the period of the Conquest in the sixteenth and seventeenth centuries AD settled in areas of palafitte occupation, coming from more distant regions, being, therefore, allochthonous in the area. More focused studies in this direction still need to be carried through.

With regard to muiraquitã made of nephrite, we can infer that it is an evidence of a complex society. This rock is rare in Brazil, being possible that its arrival to the pile dwellings occurred through long-distance commerce with peoples of the Caribbean or Colombia, places where these minerals are more abundant. Although we do not know the real meaning of these lithic materials, through comparative analogy to the cultures of the Mesoamerica, i.e., Mayan, it is very probable that

they are amulets and that certainly they belonged to the heads of the villages and was a power symbol acknowledged by everyone.

Regarding these peoples' political organization, their form of government is yet to be elucidated, if they were more complex societies or seasonal sites due to the aquatic environment. The current state of research shows that there were sites more ritualistic, as the Armíndio, where the concentration of figurines is great, in detriment of the others.

Evidences of the great territorial area occupied by these societies associated with the long time they were occupied indicate that these human groups were very well adapted to the environment. Moreover, the architectural complexity of the sites and the great number and arrangement of the pile dwellings evidence a construction guided according to center-periphery direction principle. The inferior detrition of these pile dwellings indicate that they had been lapidated for better fixing in the riverbed. A homogeneity of the material culture, as it is evident in the ceramic types and their symbolic message, is presented by paintings of the vessels and figurines, majorly predators as snakes, in addition to the cosmological representation of the *axis mundi* through the navel. Finally, it has to be considered that the contemporaneity of the sites (the majority between 930/1260 $\pm$ 30 BP), indicating a cultural homogeneity of these societies that were well adapted to the aquatic environment, leads to think about chiefdoms of great regional scale between the eighth and tenth centuries AD, coinciding, therefore, with the peak of precolonial Amazonian societies.

Acknowledgments The subject presented here composes an academic archaeological project in the institutional scope of the Department of History (DEHIS), of the Postgraduation Program in Social History (PPGHIS), and of the Laboratory of Archaeology (LARQ) of the Federal University of Maranhao (UFMA), with financial support of two agencies, one of promotion to research called Foundation of Support to Research of the State of Maranhão (FAPEMA) and another one of patrimonial protection, Institute of National Historic and Artistic Heritage (IPHAN).

Pinnacle Point: Excavation and Survey Methods

Simen Oestmo and Curtis W. Marean
Institute of Human Origins, School of Human Evolution and Social Change, Arizona State University, Tempe, AZ, USA

Introduction

The transdisciplinary project centered on Pinnacle Point (the South African Coast Paleoclimate, Paleoenvironment, Paleoecology, and Paleoanthropology Project-SACP4) has as its primary goal to develop an integrated paleoclimate, paleoenvironmental, and paleoanthropological record for the south coast of South Africa spanning 400 to 30 ka, a time that spans the origins of modern humans. The African Middle Stone Age (MSA), a Middle and Late Pleistocene stone tool phase, dominates the majority of this time span. The MSA in South Africa has gained increasing attention in debates about the antiquity of modern human behavior; some researchers arguing that the South African evidence suggests an early origin of modern behavior, while others suggesting a late origin. Resolution of these debates relies on two advances: improvements in our theoretical approach and an improvement of the empirical record in Africa. Fieldwork was initiated at Pinnacle Point (Mossel Bay, South Africa) to improve the empirical record (Marean et al. 2004).

Key Issues/Current Debates/Future Directions/Examples

Strategy

The field strategy uses state-of-the-art excavation and survey methods and techniques to obtain precise and accurate data, relying as much as possible on digital data acquisition integrated into 3D models of the "paleoscape." The paleoscape is a seamless model of land and sea that projects hunter-gatherer food resources at different climate states. We model that paleoscape with integrations of sea level and coastline change joined to species distribution modeling. A specific part of the transdisciplinary strategy is to use speleothem records to generate long, continuous, and tightly dated paleoclimatic and paleoenvironmental sequences for the MSA combined with other techniques (e.g., faunal change, phytoliths, magnetics) that enrich the environmental reconstructions.

Survey Method and Program

Pedestrian and mountain-climbing reconnaissance techniques revealed sites along the cliffs at Pinnacle Point. Today, wooden staircases and walkways provide access to most of the sites (Fig. 1). We use total stations to map all sites and landscape features, coding all visible features directly to handheld computers using drop-down menus programmed into survey software. Using both RTK GPS and direct total station measurements, all coordinates are translated directly into the South African National Coordinate (SANC) reference system (Marean et al. 2004, 2010). The data is integrated into a GIS using ArcGIS, and a 3D paleoscape model is created.

Excavation Methods and Program

Our excavation recording system is designed so that every measurement made on-site of artifacts,

Pinnacle Point: Excavation and Survey Methods, Fig. 1 Pinnacle Point landscape. The wooden walkway leads to the entrance of cave PP13B

Pinnacle Point: Excavation and Survey Methods, Fig. 2 Excavation in progress at cave PP13B. (Photographs courtesy of SACP4)

features, sections, surfaces, and everything else is recorded by total station directly to handheld computer (Fig. 2). Total stations give all finds a 3D provenience, and finds are given a unique barcode number and assigned to a square, quadrant, and stratigraphic unit. Bar code scanners are connected to handheld computers through USB cables, requiring little to no typing of specimen numbers or other observations. This significantly reduces the transcription errors that plague field

Pinnacle Point: Excavation and Survey Methods, Fig. 3 The inferred vegetation sequence from the Crevice Cave speleothem relative to southern hemisphere temperature change and major phases in the production of stone tools and use of raw materials in the southern Cape of South Africa. (**a**) The EPICA EDML d18O record (EPICA Community Members, 2006), (**b**) the Crevice Cave (Pinnacle Point) d13C (*green*) records with inferred grass regimes, (**c**) the major changes in stone tool phase, stone tool type, and raw material abundance in the southern Cape, and (**d**) the raw material abundances at archaeological site PP5-6 (Bar-Matthews et al. 2010: Fig. 11)

recording (Dibble et al. 2007). We record both ends of elongated artifacts by total station to calculate orientation and slope of artifacts within stratigraphic aggregates. We use artifact orientation to gain knowledge about site taphonomy (Bernatchez 2010). All non-plotted materials are gently wet sieved with fresh water through a nested 10-3-1.0 mm sieve (Marean et al. 2010).

We excavate within 50 cm quadrants within squares, naming them by their bearing: NE, NW, SE, and SW. Excavations within these quadrants are conducted following natural stratigraphic units (StratUnits: layers, features, etc.). These StratUnits are grouped into larger stratigraphic aggregates (layers) in the field and then checked with 3D GIS analysis. All excavator accounts of StratUnits are recorded to forms (supplemented by notebooks) and then typed into a form-based database system. Sediment volume is measured during excavation and sediment samples are taken from every StratUnit. Subsamples of the sediment samples are used to measure magnetic susceptibility (MS) used to identifying evidence for human occupation, mainly due to the use of fire at archaeological sites (Herries and Fisher 2010).

Section drawings are created by combining regular graph paper drawing with dense

measurements of all stratigraphy and features using a total station directly to handheld computer, which links the section drawing to true grid space. We then digitally rectify all our section drawing and photographs (Bernatchez and Marean 2011) to true grid space, which allows us to plot on those photographs all artifacts, dating samples, stratigraphic boundaries, and anything else removed from site (Marean et al. 2010). On-site checking of field-acquired data eliminates most potential errors.

Analysis

Optically stimulated luminescence dating (OSL), TT-OSL, and U-Th dating (also known as uranium series, U-series, 230Th/U) are used to maintain chronological control (Bar-Matthews et al. 2010; Jacobs 2010; Marean et al. 2010). Most OSL ages come from locations where we also conduct micromorphology. Micromorphology significantly enhances our ability to understand sedimentary processes that are potentially problematic for OSL. Pinnacle Point research employs micromorphology regularly, as a foundation to stratigraphic analysis in complex depositional contexts (Marean et al. 2010; Karkanas and Goldberg 2010). We rely heavily on 3D GIS integration of all data and using ages, micromorphology, and stratigraphy to develop "life histories" of the caves (Fig. 3).

Assessment of Success

Fieldwork at Pinnacle Point has yielded the earliest evidence for human exploitation of marine resources, earliest securely dated use and modification of pigment, early use of bladelet stone tool technology at PP13B by ~164 ka, and early evidence for heat treatment of lithics at sites PP13B and PP5–6 (Marean et al. 2007; Brown et al. 2009; Thompson et al. 2010; Watts 2010). We have published, to date, the highest resolution speleothem record for Africa for the MSA for the time span 90–53 ka, which provides us with an unprecedented understanding of changes in rainfall and vegetation (Bar-Matthews et al. 2010). In addition, our tightly collaborative research has allowed us to detect correlations between the coastline distances, strontium isotope ratios in the speleothems, and the abundance of shellfish in coastal sites (Fisher et al. 2010; Jerardino and Marean 2010). We attribute a portion of our success to the reliance on digital acquisition of data, which allows fast- and high-quality analysis of field data, and the synergy created by our transdisciplinary approach, which allows quick insights that cross the traditional boundaries of science.

Piotrovsky, Boris B.

Vladimir I. Ionesov
Department of Theory and History of Culture, Samara State Academy of Culture and Arts, Samara, Russia

Basic Biographical Information

Boris Borisovich Piotrovsky (1908–1990) was a famous Soviet Russian academic, historian, orientalist, and archaeologist who studied the ancient civilizations of Urartu, Nubia, and Scythia. He is well known as a key investigator in the study of the Urartian civilization of the southern Caucasus. Boris B. Piotrovsky's main works are devoted to the history, culture, and art of the Caucasus and the Ancient East, in particular the states of Urartu, and to questions of the origin and development of the ancient history of Armenian people. For most of his life, Boris Piotrovsky had connections with the State Hermitage Museum in Saint Petersburg. From 1964 until his death, he was director of this museum.

Piotrovsky was born in Petersburg in 1908. In 1929, being the student of a last year of historical and linguistic faculty of the Leningrad State University, B. B. Piotrovsky went to work in academy of history of material culture (Institute of Archaeology of the Academy of Sciences), in the sector of language, which academic N.Ya.Marr directed at that time. In 1930, B. B. Piotrovsky graduated from the university, and a year later he began to work in the hermitage as a scientific fellow.

Piotrovskyspecialized in the history and archaeology of the Caucasus region, and in the beginning of the 1930s, he began to acquaint

himself with Urartian civilization. Thanks to the long-term (from 1939 to 1971) joint excavations of the Academy of Sciences Armenian Soviet Socialist Republic and State Hermitage under the supervisor of B. B. Piotrovsky, the ancient city of Teyshebaini was studied. This site is one of the most interesting and most comprehensively studied monuments of Urartian civilization.

From 1953 to 1964 B. B. Piotrovsky was the leader of the Leningrad Department of the Institute of Archeology of Academy of Sciences of the USSR, and in 1964 he became the director of the State Hermitage. He remained in this position for 26 years until his death. Boris Piotrovsky combined scientific activity and administrative work with pedagogical and public work. From 1966 until his death, he was head of the Department of the Ancient East at Faculty of Eastern Studies in Leningrad State University.

Major Accomplishments

Since his student years, B.B. Piotrovsky took part in various archaeological expeditions in the North Caucasus. Archaeological study of the complex analysis and historical reconstruction of Urartu's monuments for many years becomes the main direction of his scientific activity.

The sphere of scientific interests of B. Piotrovsky was extraordinarily wide and various: archaeology and the Ancient East, questions of social and cultural history, the history and collections of the Hermitage, and the people who have made a significant contribution to creation of the museum.

Piotrovsky was director of the 1939 excavations that uncovered the Urartian fortress of Teishebaini in Armenia. The antiquity was hidden for many centuries under "a red hill" and now is one of the most interesting and most comprehensively studied monuments of Urartian civilization. Karmir Blur means "red hill" or "red fortress" (Armenian: Կարմիր բերդ meaning "red fortress"). It is a fortified Urartian settlement, which was destroyed in the beginning of sixth century BCE. Evidence found there has been a key to understanding the Urartian civilization. His well-known excavation of a fortress on a hill Karmir Blur about Yerevan opened to the world the new ancient state of Urartu and was a great discovery.

The results of expeditions were described in detail by B. B. Piotrovsky in his scientific works – archaeological reports on Karmir Blur's excavation (1950, 1952, 1955) and monographs: *History and Culture of Urartu* (1944), *Karmir Blur* (1950–1955), and *Art of Urartu by the Eighth–Sixth Centuries BC* (1962).

Since the beginning of the Great Patriotic War in 1941–1942, B. B. Piotrovsky wrote in Leningrad the book *History and Culture of Urartu*, which was published in 1944. For this work he was awarded the scientific degree of the doctor of historical sciences (1944) and the State Prize of the USSR (1946).

After the Great Patriotic War, Piotrovsky continued research in Karmir Blur, and in 1956 he had an opportunity to visit Egypt. Later, in 1961–1963, he headed the work of the International Archaeological Expedition to Nubia, in the territory flooded by waters of the Aswan Dam under construction.

The name of B. B. Piotrovsky has entered into the Soviet and world historical science about the ancient world. Boris B. Piotrovsky possesses numerous works on ancient history, archaeology, art of Transcaucasia, the North Caucasus, Central Asia, and also on history and culture of ancient Egypt, finding the deserved recognition as in Russia and abroad. Experience and knowledge allowed B. B. Piotrovsky to carry out more than 50 scientific archaeological expeditions fruitfully. The scientific results of excavations at Urartian fortress on a hill Karmir Blur in Armenia, near Yerevan, which passed from 1939 to 1941, were especially significant.

These were not Piotrovsky's sole contributions to the field of archaeology, however. Piotrovsky worked elsewhere in the Caucasus, especially on the Scythian culture. In 1961, he became the head

of an expedition of the USSR Academy of Sciences to study Nubian monuments in Egypt.

B.B. Piotrovsky was elected as a full member of Academy of Sciences of the USSR on Department of History (History of Culture) in 1970, was a full member of Academy of Sciences Armenian Soviet Socialist Republic in 1968, and a member correspondent of the Bavarian Academy of Sciences, the British Academy of Sciences, Royal Academy of Morocco, and an honorary member of fifteen other foreign academies and scientific societies.

In his lifetime, B.B. Piotrovsky published more than 200 works in the fields of archaeology, history, and art.

Pirazzoli t'Serstevens, Michéle

Aedeen Cremin
Yass, NSW, Australia

Basic Biographical Information

Michèle Pirazzoli-t'Serstevens (1934–2018) was the first professor of Chinese archaeology in Western Europe and the author of several important works on China's archaeology.

Born in France, of a prominent Franco-Belgian family, she lived most of her life in Paris. At university she studied Oriental languages (1956–1957), principally Vietnamese and Chinese, but also Japanese, Hindi, and Tamil. She went on to study Indian and East Asian art at the École du Louvre (1957–1960) during which time she started work at France's Museum of Asian Arts, the Musée Guimet. She spent a year at Peking University (1964–1965), returning to the Guimet as an assistant curator (1965–1969) and then curator (1969–1977). After some time in Tokyo (1974–1975), she was also appointed curator of the Musée d'Ennery, a Parisian house museum with a substantial collection of eighteenth- and nineteenth-century Japanese decorative arts.

In 1971 she completed a PhD thesis on China's Dian culture. She was by then married and had taken the name of her husband, the geomorphologist Paolo Pirazzoli (1939–2017). She taught at the École du Louvre (1968–1977) and in 1977 took up the newly created chair of Chinese archaeology at

the École Pratique des Hautes Études (EPHE) at the Sorbonne, where she remained until 2002.

As an archaeologist Pirazzoli-t'Serstevens undertook fieldwork in Cambodia, at the pre-urban site of Mimot and at an early royal capital at Sambor Prei Kuk (1961–1962). In later years she worked with French excavation teams in Bahrain (1978), Oman (Suhar 1982), the United Arab Emirates (Ras al Khaimah/Julfar 1994), and Brunei (1998), analyzing the Chinese export ceramics found there.

Michèle Pirazzoli-t'Serstevens published numerous works on Chinese archaeology and was for over 30 years on the editorial board of the journal *Arts Asiatiques*. She received two national honors, Chevalier de l'Ordre National du Mérite (for civil achievement) and Officier dans l'Ordre des Palmes Académiques (for academic distinction) and two book prizes, Prix Delalande-Guérineau (1976) for her book on Dian and the Prix Giles (2009) for *Giuseppe Castiglione*, about the Jesuit artist working at the court of the Qing emperors.

Major Accomplishments

Michèle Pirazzoli-t'Serstevens was a writer of impeccable scholarship and noted for the clarity of her writing. She made Chinese scholarship accessible to Western archaeologists through her teaching, writing, and the works she reviewed. She had a particular understanding of connected histories and of the interactions between China and its neighbors and demonstrated these connections through many studies of art and artifacts, extending her inquiry to the broader context of cultural exchange over the past 2000 years (1994, 2007, 2008, 2011).

Chinese archaeology was beginning to intensify in the 1960s when Pirazzoli-t'Serstevens was a student in Beijing. This meant that she was well placed to evaluate the astonishing early-historic finds of the 1970s: the tombs of Han princes at Mancheng, Hebei (1968), of the Marquis of Dai at Mawangdui, Changsha (1972–1974), of the Terracotta Warriors at Xian, Shaanxi (1974), of Queen Fuhao at Anyang, Henan (1976), and of the Marquis Yi at Leigudun, Hubei (1978). Her doctoral thesis was about a minority group, the Dian of Yunnan, whose bronze-rich cemeteries were excavated from 1956 on.

Pirazzoli-t'Serstevens worked principally on the archaeology of the Han (206 BCE–220 CE), an empire which vastly expanded China's territory and, briefly, held power over eastern Uzbekistan, northern Vietnam, and northern Korea. Despite that empire's collapse, trade and cultural relationships were maintained over the millennia.

The lack of congruence between the historical and archaeological records became a key point in Pirazzoli-t'Serstevens' work, and she often stressed the value of archaeology as a corrective to the acceptance of historical records, using evidence from thousands of Han-period tombs to demonstrate the gap between practice and prescription (Pirazzoli-t'Serstevens 2009). Her research was valuable not only for its content but as methodogical example for archaeologists working in other time periods and in other parts of the world.

Pitt Rivers Museum

Paul Turnbull
School of Humanities, University of Tasmania, Hobart, TAS, Australia
School of Historical and Philosophical Studies, University of Queensland, St Lucia, QLD, Australia
College of Arts, Law and Education, University of Tasmania, Hobart, TAS, Australia
HAPI, University of Queensland, Brisbane, QLD, Australia
NCIS, Australian National University, Canberra, ACT, Australia

The Pitt Rivers Museum of the University of Oxford was founded in 1884 to exhibit the anthropological collections of Augustus Lane Fox Pitt-Rivers (1827–1900).

Today the Museum possesses well over half a million objects, photographs, and manuscripts from all over the world ranging in date from prehistoric times to the present day. It is also a leading international center for research in social and cultural anthropology, and the history, theory, and practice of museum curatorship.

The Pitt Rivers Museum is noteworthy for its preserving the original arrangement and display of its possessions according to Pitt-Rivers's "typological" system of organization (Pitt-Rivers 1891, 115–116).

Pitt-Rivers was inspired by Darwin to think that human cultural history was subject to evolution in ways analogous to Darwin's theory of the evolution of animal and plant life. Hence when gifting his collections to the University of Oxford, Pitt-Rivers specified that they be exhibited and conserved in a purpose built building on the basis of their function rather than their community and place of origin, as is the curatorial norm today. His reasoning was that by arranging artifacts from different social contexts and times that were reported to be used for much the same purposes, the gradual evolutionary trajectory of objects from primitive "type" through progressively more sophisticated forms could be clearly seen.

In achieving this aim, Pitt-Rivers enjoyed the support of Edward Burnett Tylor (1832–1917), the keeper of Oxford's University Museum since 1883, and also Henry Nottidge Moseley (1844–1891) who as professor of human and comparative anatomy was responsible for the ethnographic collections at the University Museum. Tylor played a major part in the disciplinary coalescence of anthropology in Britain. He was instrumental in creating the anthropological section of the British Association, and in 1884 served as its first president. The year after his appointment as keeper of the University Museum, Tylor became Oxford's first reader in anthropology, having won a substantial reputation as a leading figure in European anthropological circles, largely on the basis of his greatly influential two-volume work, *Primitive Culture: Researches into the*

Development of Mythology, Philosophy, Religion, Art, and Custom (1871).

Tylor, however, differed from Pitt-Rivers and Moseley in more cautiously accepting Darwin's argument for man's evolutionary descent from earlier biological forms. He believed, unlike Pitt-Rivers, that cultural beliefs and practices were not necessarily subject to tests of fitness comparable to the operation of natural selection. Tylor believed that aspects of culture could survive long beyond whatever contribution they may have once made to the cohesion and advancement of a society was exhausted. Also, unlike Pitt-Rivers, Tylor was open to the possibility that aspects of culture could be the result of exchanges of people, ideas, and technologies, rather than autochthonous evolutionary processes.

The influence of Pitt-Rivers's collections on the exhibition of ethnological artifacts actually dates from before the Museum was first opened (in part) to the public in early 1887. When studying at Oxford in 1885, Walter Baldwin Spencer (1860–1929), who was to become internationally known by the turn of the twentieth century as the foremost authority on the anthropology of Indigenous Australia, spent a month unpacking and arranging Pitt Rivers's collection under the supervision of Moseley and Tylor. Another important figure in the history of Australian anthropology who was influenced by assisting in the transfer of Pitt Rivers's collections to Oxford was Walter Roth (1861–1933), who was to produce the most significant body of ethnographic reportage on Indigenous people in Northern and Western Queensland at the turn of the twentieth century.

Pitt-Rivers's collections served as an important resource for the teaching of both anthropology and archaeology at Oxford until the early decades of the twentieth century. Henry Balfour (1863–1939), who was appointed curator in 1890, used the collection extensively in publishing many scholarly articles tracing the "evolutionary development" through history and across different culture of particular objects. Balfour also actively solicited donations to the collections from past students who became colonial administrators in various parts of the British Empire. Likewise, Robert Marrett (1866–1943), who, on the retirement of Tylor in 1910, was appointed reader in social anthropology and was to be acting professor of social anthropology until the late 1930s, equally encouraged Oxford graduates to help enlarge the museum's holdings.

After the end of the Second World War, the evolutionary paradigm finding concrete expression in the organization of the museum's collections came to be challenged by younger anthropologists for whom the prime goal of the discipline was to understand through fieldwork how particular social systems were sustained and reproduced, and regularities might be observable in social change across societies. Even so, the collections of the Pitt Rivers museum continue to this day to be arranged by types of object, albeit with an emphasis on the different cultural contexts in which specific items serving similar social ends have been created.

Pitt-Rivers was an early convert to Darwin's evolutionary vision of nature and fascinated by its implications for understanding human societal and cultural development. His prime contribution to the fields of anthropology and archaeology was the creation of collections of ancient and contemporary weapons, tools, and other artifacts which he saw as illustrative of the evolution of human culture.

"Collecting is an hereditary disease, and I fear incurable," humorously observed by Augustus Wollaston Franks, founder of the British Museum's famed ethnographic collections in 1866 (Caygill and Cherry 1997, 318). Pitt-Rivers was similarly moved to jocularly describe his lifelong devotion to collecting objects of esthetic and cultural as an affliction or madness. In his case, the impulse to collect was gratified by the acquisition of historic firearms during his service in the Grenadier Guards, which saw his appointment in 1835 as an instructor at the newly established Hythe School of Musketry. By the time Darwin published his *Origin of Species* in 1859, Pitt-Rivers had actively collected other kinds of weaponry and tools.

Reading Darwin and Herbert Spencer's writings on social evolution, Pitt-Rivers was convinced that human culture had become progressively more sophisticated in ways comparable to the emergence by evolution of more complex life-forms. This conviction thereafter was the intellectual bedrock of his anthropological and archaeological research. Indeed, Pitt-Rivers can be said to have been truer to Darwin's "long argument" for evolution by natural selection than many of Darwinians in that he followed the naturalist in believing that the evolution of life-forms was slow and linearly incremental. This was in mark contrast to other leading followers of Darwin, such as Thomas Henry Huxley, for example, who believed it to be possible that environmental forces could affect organisms so as to cause radical changes in morphology and physiology.

Even so, Pitt-Rivers had none of Darwin's reticence when it came to drawing analogies between biological and cultural evolution. He also thought, like the Darwinian anatomists George Rolleston and Alexander Macalister, that evolution is a "purposeful," teleological process. As he observed in a lecture he delivered at the Royal Institution of Great Britain in 1875, "...the highest achievements of science, even the highest practical achievements, would never have been reached by the mere utilitarian. There is a force within us by which we are moved in the direction of acquiring knowledge for its own sake and for the sake of truth, regardless of any material advantage to be derived from such knowledge" (Pitt-Rivers 1906, 21).

Pitt-Rivers stood with Herbert Spencer in the founding of an influential tradition of viewing humanity through the lens of purposeful cultural evolutionism. However, Pitt-Rivers's contribution was primarily his museology rather than his writings.

His rationale for making his collections publicly viewable, starting with the loan of objects to Bethnal Green Branch of the South Kensington Museum in 1874, was that the path to achieving true social and moral progress was by enhancing public understanding of humanity's evolutionary history, and he believed that a particularly effective way of doing this was by museums displaying artifacts so as to illustrate the emergence and gradual improvement of the human condition. Pitt-Rivers's evolutionary museology was also

inflected by his social conservatism. As he observed in 1891, "The law that Nature makes no jumps, can be taught by the history of mechanical contrivances, in such a way as at least to make men cautious how they listen to scatter-brained revolutionary suggestions" (1891, 116).

In arranging his collections for research and display, Pitt-Rivers's evolutionism led him to develop what he termed a "typological" system of organization (1891, 115–116). This involved associating ethnographical and archaeological artifacts on the basis of function rather than their community and place of origin, as is the curatorial norm today. Hence when Pitt-Rivers displayed artifacts, for example, weapons, he placed them in a series which he saw as showing their gradual linear evolution from an earliest known primitive "type" through ever more sophisticated forms. And as we can now clearly see, what Pitt-Rivers and fellow sociocultural evolutionists regarded as illustrative of the history of particular technologies served to implicitly privilege Eurocentric perceptions of human diversity and the legitimacy of contemporary colonial ambitions.

After inheriting valuable agricultural lands in 1880, Pitt-Rivers established a museum on his estate in Farnham, Dorset. The following year, he began negotiations with the University of Oxford that eventually saw his collections held by the South Kensington Museum transferred to a purpose-built museum that was fully open to the public in 1892.

By the 1880s, Pitt-Rivers was also well known for his archaeological research. His surveys of the prehistoric sites, the first of which he completed during military service in Ireland, secured his election as a fellow of the Society of Antiquaries in 1864. Thereafter he surveyed and excavated sites in various parts of England, notably discovering implements together with animal bones of the Paleolithic era in gravel deposits in the Thames Valley. In 1871, he was elected president of the Society of Antiquaries and made a fellow of the Royal Society in 1876. Such was his reputation in contemporary scientific circles that he was appointed as the first Inspector of Ancient Monuments in 1883 after John Lubbock, 1st Baron Avebury, persuaded the United Kingdom's Parliament to give prehistoric and other ancient structures legal protection.

While active as Inspector of Ancient Monuments, Pitt-Rivers also investigated sites on his own property lands in Dorset and Wiltshire. His wealth enabled him to undertake systematic excavations of prehistoric, Romano-British, and medieval sites on his Cranborne Chase estate. Many of the artifacts from these excavations were displayed in his Farnham museum.

Pitt-Rivers's cultural evolutionism led him to record the findings of his excavations in what, during the late Victorian era, was unusually close attention to contextual detail. It also gave rise to his drawing on his vast knowledge of the construction and uses of contemporary artifacts in interpreting the many implements and other prehistoric objects found in the course of his archaeological investigations. By the 1920s, his evolutionism was viewed by many in anthropological and archeological circles as explanatorily crude.

Plain of Jars Archaeological Landscape

Julie Van Den Bergh
Archaeological Assessments Ltd, Hong Kong, Lamma Island, Hong Kong

Introduction

The remote plateau of Xieng Khouang in Laos is home to one of the most enigmatic and fascinating archaeological landscapes in Southeast Asia. Clusters of megalithic jars, ranging in size from 1 to 3 m in height and diameter, dot the lower foot slopes and surround the central plain. The limited archaeological research carried out to date indicates that the stone jars were part of Iron Age burial practices which occurred and evolved at the crossroads of the two major eco-cultural systems of Iron Age Southeast Asia: the Mun-Mekong System and the Red River/Golf of Tonkin System.

The strategic importance of the Plain of Jars in the region was highlighted during the Siamese-Dai Viet conflicts of the late eighteenth to late nineteenth century and again during the Indochina Wars. It was during the Second Indochina War that the United States carpet bombed Xieng Khouang and left a deadly legacy of unexploded ordnance (UXO). UXO has been the main cause of poverty in the province as it severely hampers economic development; it has also resulted in limited archaeological research.

A UNESCO-Lao government initiative called *Safeguarding the Plain of Jars Project*, which commenced in 1998, has compiled a Geographical Information System database of 89 sites within Xieng Khouang province (www.unescobkk.org/culture/pdj/). The database provides information on location, form, material, and conservation status for each individual jar, as well as overall site descriptions and information on 7 or 8 locations regarded as jar quarry and manufacturing sites. The identification of multiple sites allowed researchers to develop a better understanding of the locations chosen and the technical know-how behind jar production (Baldock and Van Den Bergh 2009). The project was set up as a comprehensive effort to rehabilitate the Plain of Jars, and initially, with the financial assistance of the New Zealand government (NZAID), seven jar sites were cleared of UXO and prepared for community-led heritage management and tourism development.

Definition

Plain of Jars is an organically evolved archaeological landscape in the central east of Lao PDR. The landscape consists of clusters of megalithic jars and associated features which are thought to reflect ancient beliefs in birth, life, death, and rebirth. The typical attributes of a jar site comprise stone jars, stone disc-shaped grave markers, stone lids, and secondary burials with pottery, stone, bronze, or iron grave goods. The latter components, together with the site locations, decorative expressions, and limestone cave at site 1 and quarries, form the Plain of Jars Archaeological Landscape.

Although the jars are largely undecorated, the range of jar forms and modifications in manufacturing process may indicate either individualistic expressions of the carvers or simply changing needs, that is, a transition from ritual excarnation to cremation. Among the few decorations adorning jars and stone discs are human and animal *bas-relief* figures, including monkeys, tigers, and possibly frogs.

The secondary burials surrounding the stone jars are typically simple with plain urns, some stone tools, stone beads, plain or incised pottery, and a few metal artefacts such as bronze bells, bronze or iron wire bracelets, and iron knives.

Historical Background

Investigation History

The first systematic archaeological investigations at the Plain of Jars were conducted in 1931–1933

by Madeleine Colani under the auspices of the Ecole Française d'Extrême Orient in Hanoi. She recorded around 20 sites, excavated a number of them, and published two volumes with her findings a few years later (Colani 1935).

No further academic research was conducted until November 1994 when Professor Eiji Nitta of the Kagoshima University in collaboration with Lao Archaeologist Thongsa Sayavongkhamdy excavated, surveyed, and mapped the main site at Ban Ang (Nitta 1996). Mr. Sayavongkhamdy then continued to excavate several trenches at sites 1–3 in 1996 (Sayavongkhamdy and Bellwood 2001).

Limited archaeological investigation led by Ms. Van Den Bergh and Mr. Samlane Luangaphay took place as part of the unexploded bomb clearance of the seven jar sites in 2004–2005 and 2007. During such work, a methodology for archaeological data retrieval during UXO clearance was developed in collaboration with UK-based charity Mines Advisory Group. The methodology allows for safe information gathering during excavation for unexploded bombs (Rogers and Van Den Bergh 2008).

Excavation results since the 1930s have contributed only modestly to the further interpretation of Plain of Jars as a collection of Iron Age burial sites. Recent archaeological work has confirmed the presence of secondary burials surrounding the jars and also proved that the stone jars are contemporary with the burials. The dating of the Plain of Jars remains in question as the few AMS and C14 dates so far obtained fall outside of the accepted Southeast Asian Iron Age range (Sayavongkhamdy and Bellwood 2001: 108; Van Den Bergh 2007: 5), while the net-patterned pottery and human decorative *bas-relief* motifs are similar to fifth-century BCE to third-century CE examples from southern China. Although an Iron Age date for the Plain of Jars is generally accepted, Nitta suggested the resin covered urns should be dated to the end of the first millennium CE (Nitta 1996: 17).

A working hypothesis put forward by Dr. Pamela Rogers and Dr. Richard Engelhardt (2003) proposed that the stone jars functioned as "distilling" vessels for human corpses. The ritual decomposition was then followed by secondary burial. Traditional Southeast Asian royal mortuary practices provide modern parallels that symbolize the transition of the deceased into the spiritual world. The hypothesis is supported by the secondary burials found around the base of stone jars and scant evidence of human bone and teeth inside the jars recorded by Colani.

Legislative Framework and Protection Mechanisms

The Plain of Jars was put forward by the Lao Government in 1992 as a tentative UNESCO World Heritage Site. The government recognized the site as a national heritage in 1993 after its registration by the Provincial Department of Information and Culture, and its protection status was thus defined and subsequently enshrined in the Heritage Law of 2005.

Key Issues/Current Debates

The key issue for the Plain of Jars is to put in place mechanisms to ensure the protection of this vast, complex, but little understood landscape in the context of a poor, predominantly rural, developing country (Van Den Bergh 2011). Currently the 3 main sites are managed by local provincial and district governments, and these are the only jar sites that generate limited income from tourist entrance fees. The one euro entrance fee covers the services of a ticket seller and basic maintenance of the site (s) by the community. The central or provincial governments lack sufficient funds to provide dedicated protection for the numerous sites.

A further constraint is the obvious imbalance between the Lao PDR's small number of national archaeologists, and the human resources actually needed to deal with the complex, widespread, and often remote Plain of Jars sites. Community-based heritage management is a significant step forward in front line protection, but the training of competent personnel at provincial and district level is crucial if sustainable management and periodic monitoring of sites are to be ensured.

The Plain of Jars Archaeological Landscape has a high level of integrity with the sites having suffered mainly from benign neglect – the obvious exception being the carpet bombing of the province during the Second Indochina War. The end of the first decade of the twenty-first century has, however, been marked in Xieng Khouang province by the accelerated development of agriculture, road networks, and mining exploration. Development without thought for the preservation of the entire archaeological landscape may save the most famous and accessible sites at the cost of losing the very essence of the Plain of Jars: an archaeological landscape reflecting the extensive and elaborate mortuary practices of a long-disappeared civilization with strong cultural exchanges evidenced in the form and location of jar sites across its entire extent.

International Perspectives and Future Directions

Megalithic jars are not unique to Laos and the Plain of Jars. In 1929 Mils and Hutton (as cited in Colani 1935: 223–236) recorded four stone jar sites in the Cachar Hills of Northeast India, and "stone vats" have been recorded in the valleys of Bada and Besoa, Central Sulawesi, and Bima, Sumbawa Island in Indonesia. Nevertheless, when considered collectively, the well-understood strategic importance of the plateau, the integrity, authenticity of the landscape, and the resulting high research values make the Plain of Jars Archaeological Landscape a good candidate for UNESCO World Heritage Listing.

In addition to contributing to our understanding of Southeast Asian prehistory, the sites have great potential for education and the development of community-led heritage tourism, which was recognized by UNESCO, the Lao government, and NZAID in Phase IV of Safeguarding the Plain of Jars Project 2006–2010.

The UXO problem, however, must be acknowledged, and bomb removal efforts should continue to focus on sustainable heritage development.

Plant Domestication and Cultivation in Archaeology

Kristen Gremillion
Department of Anthropology, The Ohio State University, Columbus, OH, USA

Introduction

Plant domestication and cultivation are key concepts for archaeologists who study food-producing societies. Food production takes many forms, ranging from behaviors such as controlled burning that increase harvest yields to highly integrated agricultural systems supporting large populations. Dependence on food production has implications that ramify throughout sociocultural systems and played a key role in the development of corporate land tenure, social mechanisms for control of food surplus, and social hierarchies worldwide. In addition to its cultural significance, plant domestication is the ultimate basis for many of the human behaviors that have modified ecosystems on a global scale.

Definition

Most broadly, plant domestication can be defined as evolution under human management. By definition, then, domestication involves some change in gene frequencies within the population in question. Gene frequencies change because the phenotypic traits they express – such as unusually large seeds – are favored by selection in the modified habitats created by human activity. Domestication is sometimes perceived as purposive, but in fact it can be initiated as a result of human modification of the environment without any conscious planning. Phenotypic change within domesticated populations may be visible in the archaeological record, depending on the plant tissues affected and their likelihood of preservation. The study of ancient DNA has made it possible to pinpoint significant mutations and track their history in some taxa.

Domestication represents a continuum, and scholars have acknowledged this fact by using such terms as "semidomesticated," "fully domesticated," and "initial stages of domestication." Morphological departures from the state characteristic of natural populations provide one set of indicators that domestication was underway. However, human management does not always leave such clear morphological signals.

Whereas domestication is a particular type of evolution in which selection under human influence plays a major role, cultivation encompasses a suite of behaviors involved in managing plant resources, including but not limited to clearing, burning, plowing, selective breeding, planting, and harvesting. Domestication is an evolutionary process or relationship, whereas cultivation is a type of human activity. The two are closely related and often co-occur, but they are clearly different types of phenomena. There is more ambiguity regarding the difference between the two when "domesticated" and "cultivated" are used as modifiers, as in "domesticated plant." Archaeobotanists usually distinguish between cultivated plants, which are tended by humans but may or may not have undergone selection as a result, and domesticated ones, which must meet the additional criterion of having been morphologically and genetically altered from the wild state.

Domestication is seldom viewed today as an intentional, goal-directed form of technology in which humans impose their will on plants and animals to create new, culturally modified forms. Instead, domesticated species are recognized to be active participants in a mutualistic relationship that has evolutionary consequences for both

partners. Highlighting and reinforcing this view is the recognition that humans are not the only organisms that domesticate, as research on social insects has revealed (Rindos 1984). The nature of the domesticatory relationship in terms of human control, the degree of phenotypic modification of the domesticate, and the significance of evolutionary and environmental constraints upon the coevolutionary process vary considerably depending upon the species involved.

Historical Background

Historical Geography and Evolution of Domesticates: The Nineteenth Century

The first in-depth scientific studies of plant and animal domestication were undertaken in the nineteenth century. Most famously, Charles Darwin used the development of distinct varieties of domesticates as an analogy for natural selection (Darwin 1859). He skillfully took the reader through the argument, which provided familiar points of reference from animal breeding – the breeder's decisions to enhance some traits and suppress others, the principle of inheritance (by which like produces like) and the appearance of "sports" (unusual phenotypes). By the time he deftly replaced the pigeon fancier with nature as the selecting agent, the basic elements of the principle of natural selection had been presented, accompanied by a body of supporting evidence. Darwin subsequently published a two-volume treatise in which he explored the causes of phenotypic variation in domesticated animals and plants (Darwin 1868).

Darwin relied for much of his data on the work of Alphonse de Candolle, who aimed to identify the geographical origins of crop plants based on their then-current geographical distributions, historical information, languages, and archaeology. First published in 1855, his major work predated the publication of Darwin's *Origin* by several years. However, even the later (substantially revised) 1888 edition (De Candolle 1886) has little to say about the evolutionary processes by which plants become domesticated. De Candolle did, however, have a keen interest in the archaeological record as a source of evidence for ancient crops and their history. He knew of the excavations of Oswald Heer at the Swiss lake dwellings and was acquainted with the desiccated seeds and other plant parts that had been discovered in Egyptian tombs (De Candolle 1886: 11). Archaeobotany was still a young discipline, but in the years to come, archaeologists would begin to appreciate its potential for documenting domestication.

Archaeology and Plant Domestication: The Early Twentieth Century

One of the first archaeologists to take an explicit interest in plant domestication and agricultural origins was Rafael Pumpelly, whose excavations at Anau in Turkey investigated climate change in relation to early food production (Zeder et al. 2006a). Archaeological research in the Near East has been, and continues to be, a major source of paleoenvironmental and archaeobotanical data on plant domestication.

With the realization that even minute plant parts such as seeds could be recovered from archaeological soils, archaeobotanists began looking more closely at the distinctive morphological traits that differentiated domesticated plants from their wild relatives. The University of Michigan Museum of Anthropology's Ethnobotany Laboratory made major contributions to the metric study of the seeds and fruits of native eastern North American domesticates, such as the sunflower (*Helianthus annuus* L.) and marsh elder (*Iva annua* L.). This work, begun by Melvin Gilmore and his student Volney Jones, was carried on by subsequent generations of ethnobotanists. This Michigan school of paleoethnobotany was influenced by the work of botanist Edgar Anderson, whose 1952 book *Plants, Man, and Life* presented what came to be known as the "dump-heap theory" of plant domestication (Smith 1992). Anderson recognized that human activity enriched soils and disturbed vegetation in ways that encouraged the colonization of campsites by weeds, many of which were cultivated as food sources. Many later archaeologists and

archaeobotanists were to find this model useful in explaining how and why domestication began. Anderson's vision of domestication as a purely incidental consequence of unplanned environmental modification by humans was to become an appealing alternative to the idea that domestication was a calculated innovation.

In plant science, the work of Vavilov (1992) in the early part of the twentieth century was an important foundation for later studies of the geographical origins and dispersal of cultivated plants. Vavilov proposed that geographical origins of crop species could be pinpointed by looking for high levels of diversity in inherited traits. Although the center of diversity/point of origin correlation has not held up well over subsequent years, Vavilov's work continues to be a point of comparison for geneticists and archaeologists currently examining crop origins.

Ecological Approaches: The 1960s and 1970s

Human ecology and systems theory were attractive paradigms for archaeologists working on the origins of agriculture. These approaches informed the work of North American archaeologists such as Kent Flannery, who initiated multidisciplinary projects that laid the groundwork for the scientific study of plant domestication in both Mexico and the Near East. Across the Atlantic, the economic prehistory school was flourishing, producing data-rich and theoretically informed studies of ancient plant domestication. Flotation recovery of archaeological plant remains using fine screens was yielding assemblages of unprecedented size and quality, stimulating archaeobotanists to investigate the morphological correlates of domestication by measuring seeds and fruits. In eastern North America, this work led to widespread recognition that the domestication of native plants had preceded by at least two millennia the introduction of maize from Mexico (Smith 1992, 2006; Zeder et al. 2006a).

In agricultural sciences, Jack Harlan revived Vavilov's centers of domestication, modifying the original model to acknowledge the true complexity of crop origins and dispersals by recognizing primary and secondary centers of domestication as well as noncenters (Harris 2007). Harlan along with colleagues in botany and crop sciences began to define the effects of cultivation on natural selection in plant populations. A rigorous model of the "adaptive syndrome" of domestication in seed crops was beginning to crystallize (Harlan et al. 1973).

Domestication as Coevolution: The Late Twentieth Century

By the 1980s, archaeologists and archaeobotanists had embraced an explicitly evolutionary understanding of domestication. Multidisciplinary approaches to domestication origins and processes were widespread and gaining momentum. Researchers interested in the question of morphological change under domestication turned increasingly to metric analysis of seeds and fruits, an effort fueled by the accelerated recovery of plant remains by flotation. In eastern North America, Bruce Smith demonstrated that goosefoot (*Chenopodium berlandieri* L.) was a domesticate by applying the evolutionary understanding of selection under domestication previously developed by Harlan et al. (1973). His work exemplifies the synthesis of new methods (such as scanning electron microscopy and direct accelerator dating of plant material) with evolutionary and ecological theory (specifically, the adaptive syndrome of domestication and Anderson's dump-heap model). Smith applied his understanding of plant domestication as coevolution to explain archaeological patterns in eastern North American riverine environments of the middle Holocene (Smith 1992). Coevolution became an influential concept in many regions as archaeologists grappled with the problem of how and why plant domestication emerged from straightforward predation. The continuum of human-plant interaction envisioned by David Harris and revised over several decades continues to influence theories of plant domestication (Fig. 1). In light of this ethnographically informed view of the broad spectrum of human behaviors affecting plant populations, the dichotomy separating domesticated from wild was increasingly untenable.

The theory of plant domestication as coevolution was systematically set out in a monograph by

Plant Domestication and Cultivation in Archaeology, Fig. 1 A model of the foraging-to-agriculture continuum developed by David Harris and modified by Fuller (2007). *Shaded areas* represent stages of pre-domestication cultivation. The *bottom row* indicates archaeobotanical signatures associated with each stage (Creative Commons Attribution Non-Commercial License (http://creativecommons.org/licenses/by-nc/2.5/))

David Rindos, an American scholar with a diverse background including a Ph.D. in Anthropology and Evolutionary Biology and an M.S. in Botany, both from Cornell. Rindos' 1984 book (Rindos 1984) was read with great interest by many archaeologists and ethnobotanists. Its influence was not universal, in part due to his insistence that human intention was not a proper ingredient in an evolutionary theory of domestication. He emphasized instead the mutualism that develops when animals become dispersal agents for plants. His model of agricultural expansion was largely ignored. However, Rindos forced researchers to question many of their assumptions about domestication, including its definition in terms of morphological and genetic markers. He did this by stretching the definition of domestication to its breaking point, including every instance of animal/plant mutualism, including ant "agriculture." Rindos' view of the continuum from generalized to specialized to agricultural domestication was not widely adopted in its original form. However, his contention that initial domestication did not require explanation because it was a natural outgrowth of evolved dispersal relationships seems to have struck a chord with many researchers.

Domestication in Twenty-First-Century Archaeology: A Prologue

A number of trends and issues can be identified in the contemporary study of plant domestication and cultivation in archaeology. Morphology is losing its status as the sine qua non of plant domestication; researchers realize that the diverse trajectories of domestication demand flexible criteria that may include landscape modification and dispersal of domesticates into new habitats and regions. Genetic studies have become key tools for tracing crop origins and dispersals. Starch grains and phytoliths offer new opportunities for documenting ancient domesticates. Current debates over explanation center on the choice of appropriate models and frameworks from evolutionary ecology, niche construction theory, and developmental biology.

Key Issues/Current Debates

Documentation of Domestication in the Archaeological Record

For annual seed crops, the adaptive syndrome of domestication has stood the test of time. Morphological criteria that can be securely linked with selection under domestication continue to have great value, particularly when macrobotanical remains are the target of study. For example, an increase in seed and fruit size has long been known as a response to intentional selection of seed stock but can also occur by way of seedling competition in modified soils (Table 1). Size can easily be assessed with simple measurements of length, width, and thickness. Indicators of the loss of germination dormancy may be more difficult to observe. In *Chenopodium*, thick seed coats that inhibit germination tend to be reduced or lost under domestication. Measurements of seed coat thickness must be done using high-resolution, high-magnification microscopy. The trait of shattering to disperse seeds is qualitative rather than quantitative. For example, in cereals the abscission layer that permits the ripe seed cluster (spikelet) to fall from the parent plant is lost. The resulting pattern of breakage – across the rachis, the stalk that anchors the grass seed cluster to the parent plant – is archaeologically distinctive (Pickersgill 2007; Fuller et al. 2012).

Comparisons designed to differentiate domesticated from non-domesticated populations (or semidomesticated ones) should be made between populations or samples, since variants exhibiting domesticated-type morphology may be present at low frequencies even in wild stands. Simultaneous ripening, for example, might be assessed by measuring variability in seed size within a single context or on a bundle of infructescences (fruit clusters) harvested together and preserved in a cave or rock-shelter.

For plants that are cultivated for their underground storage organs (USOs), documentation of domestication can be difficult. These plants are propagated clonally, with some sexual reproduction to maintain variation. The parts consumed are nonreproductive tissue consisting mainly of starch. Fortunately, the size and morphology of starch grains and phytoliths have the potential to reflect selection under domestication, although it is not always clear that these phenotypic changes have a genetic basis (Smith 2006).

Recently, morphology has been joined by genetic analysis as a method of documenting the appearance of domesticate phenotypes. This exciting development involves the study of quantitative trait loci (QTLs) that code for specific phenotypic traits. In maize, for example, domestication-related genes for plant architecture, storage protein synthesis, and starch production have been identified and their distribution studied using ancient DNA (aDNA) (Jones and Brown 2007). The locus controlling for starch quality was found to be different in aDNA from 4000-

Plant Domestication and Cultivation in Archaeology, Table 1 Selection pressures under a regime of harvesting and replanting of stored seed (the adaptive syndrome of domestication)

Specific behaviors	Selective pressure	Trait associated with domestication	Archaeobotanical signature
	Intensified seedling competition favoring rapid germination	Loss or reduction of germination inhibitors	Seed coat thin or lacking
Habitat disturbance, tilling	Intensified seedling competition favoring vigorous seedlings	Increase in food reserves for seedling growth	Larger seeds
Whole-plant harvesting	Competitive advantage of non-shattering type	Loss/reduction of dispersal mechanisms	Non-shattering spikelet morphology
Seed-beater harvesting	Competitive advantage of shattering trait	Dispersal mechanisms retained	Shattering spikelet morphology (abscission layer intact)
	Selection favoring seeds that are mature when harvested	Synchronous maturation of seeds	Low variance in seed size/few immature seeds

Sources: Harlan et al. (1973), Smith (1992), and Pickersgill (2007)

year-old cobs from the Ocampo caves in Mexico (a soft type preferred for making tortillas) as compared to 1000–2000-year-old maize from Tularosa Cave in New Mexico (a hard-kernelled form) (Zeder et al. 2006b).

With this kind of data, both morphological and genetic, accumulating from many world regions, it has become necessary to reassess the validity of phenotypic markers as the sole or primary criterion for plant domestication. Morphological change is not necessarily the "leading edge" of domestication but in some cases represents a much later outgrowth of pre-domestication cultivation (Zeder et al. 2006a; Harris 2007; Jones and Brown 2007). Domestication might also precede cultivation in the strict sense, due to unconscious forms of selection (Rindos 1984).

In light of the great variability of ecological situations that give rise to human-plant coevolution, researchers have called for a richer and more nuanced treatment of domestication. This newer view acknowledges that phenotypic and genotypic changes do not universally characterize the mutualisms between human and plant populations (Zeder et al. 2006b). To understand how these mutualisms develop, it is necessary to look beyond seed measurements and view plant management in its cultural context. Landscape management and archaeological occurrence of a plant outside of its known wild range are other non-morphological indicators of domestication in this broad sense (Zeder et al. 2006a). Plant domestication may be seen as one aspect of niche construction, by which organisms modify their environments in ways that affect the reproductive success of their offspring (Zeder 2016).

Rates of Domestication

In the view of nineteenth-century social evolutionists, agriculture was a precondition for civilization, and domestication of animals and plants was the brainchild of human ingenuity. Today, scholars recognize the importance of unconscious selection as well as selective breeding, and therefore that rapid transitions should not be expected. The domesticated vs. wild dichotomy has been largely replaced by a continuum in which coevolutionary relationships are fluctuating and sensitive to environmental and cultural influences rather than heading inevitably toward agriculture. However, questions still remain about the rate of domestication and how that rate varies between species. Are single mutations responsible for most domesticated phenotypes, or are they often influenced by multiple loci? What is the role of genes of large effect, such as regulatory genes that control growth and development? Can plastic responses to novel environmental conditions "jump start" the domestication process by revealing cryptic genetic variation? Do some harvesting methods accelerate domestication?

For a brief period, rapid rates had considerable support from harvest experiments that suggested that domestication of wild wheat and barley could have been accomplished in a matter of decades (Allaby et al. 2008). Also contributing to the rapid transition model for the Near East was the apparently sudden appearance of intensively harvested wild cereals in the early Holocene. However, accumulating archaeobotanical data indicate a much longer period of domestication, beginning with intensive seed harvesting some 20,000 years ago and continuing with pre-domestication cultivation by 13,000–12,500 BP, with the fixation of the domestication syndrome perhaps taking several thousand more years (Allaby et al. 2008). Possible reasons for the length of this process include relatively weak selection and ongoing gene flow from wild populations. The latter barrier could sometimes be removed only by removing the plant from its original range. The full spectrum of domestication syndrome traits for a species does not necessarily form a "package"; instead, changing harvesting practices or economic strategies shift selection so that different traits emerge at different times (Allaby 2010). In rice and other cereals, for example, changes in grain size and shape preceded the loss of the shattering trait; in legumes, cultivation was practiced for thousands of years before larger seeds developed (Fuller 2007). Another variable that may speed the rate of domestication is developmental plasticity, which allows for phenotypic variation without corresponding changes in the genome. In a stable environment, over time, such traits may become less responsive to

environment and become genetically fixed or "assimilated" (Piperno et al. 2017).

Although the protracted model of domestication is currently ascendant, there is some dissent on the grounds of parsimony (Abbo and Gopher 2017). There is reason to believe rapid, gradual, and punctuated scenarios are possible. A better understanding of the key genetic, environmental, and socioeconomic variables that distinguish these pathways is emerging from analysis of large data sets and formal models (Freeman et al. 2015; Gerbault et al. 2014; Ullah et al. 2015.

Single vs. Multiple Origins of Crop Plants

Since Vavilov's centers of domestication, new evidence has revealed a much more complex picture of crop origins. Modern cultivars frequently show the influence of multiple lineages from different geographical areas. Single origins for important crops have been proposed based on phylogenies that are monophyletic (possessing a single lineage). However, the interpretation of monophyly as indicating a single origin rests on the assumption of a rapid process of domestication. Allaby et al.'s (2008) simulation of evolution under domestication, however, indicated that sample size and the number of generations over which evolution occurred had strong effects on phylogenetic outcomes. Thus, monophyly is a poor indicator of single origins. The histories of many crop plants remain to be worked out, but close collaboration between archaeologists, archaeobotanists, geneticists, and other specialists has produced impressive results so far and promises to continue to do so in the future.

Explanation and the Role of Evolutionary Theory

Collaborative research and the great variability in pathways to domestication have stirred up theoretical debates as well. Recognition of this diversity has led some researchers away from generalizing explanations that frame domestication and agriculture primarily as predictable behavioral responses to the natural environment. However, there remains a keen interest in applications of evolutionary theory to explain both initial domestication and the intensification of production that sometimes follows. Debates regarding the role of evolutionary theory in agricultural origins research revolve around the importance of particular processes (such as niche construction and developmental plasticity) and the value of formal models derived from behavioral ecology (Gremillion et al. 2014). Although niche construction and models of optimal choice are both grounded in natural selection theory, some continue to insist that the latter approach is fatally flawed, among other things by its failure to acknowledge human intentionality as a causal factor (Zeder 2016). However, the field appears to be moving toward a consensus that the two approaches are complementary rather than contradictory (Stiner and Kuhn 2016; Zeanah 2017).

A key concept in evolutionary developmental biology, plasticity, is emerging as a potentially major factor in the domestication process because it can reveal cryptic genetic variation that, once expressed in the phenotype due to an environmental trigger, becomes subject to selection (Piperno et al. 2017). For example, the domesticated form of the weedy annual erect knotweed of eastern North America originated in the differential expression of genes controlling germination dormancy (Mueller 2016), and early Holocene temperatures and atmospheric conditions may have triggered changes in gene expression important in the evolution of maize from teosinte (Piperno et al. 2017).

There is also a tension between comparative and contextual approaches to domestication and agricultural origins. The comparative perspective seeks common processes and causes and attempts to generalize across diverse cultural and environmental contexts. In contrast, the contextual approach recognizes the diffuse and mosaic character of domestication and the importance of understanding its sociocultural context. It advocates strong attention to historical details, the actions of self-aware agents, and local environments as a bridge to broader forms of explanation (Vrydaghs and Denham 2007).

International Perspectives

Historical differences in the development of archaeology in North America and the UK

influence approaches to domestication. North American archaeology has been closely associated with cultural anthropology and human evolutionary studies. In the UK, prehistoric archaeology was more closely affiliated with geology and paleontology. Today, collaboration has erased or blurred these distinctions and opened up new opportunities for multidisciplinary research that takes advantage of many lines of evidence. An example of this trend is the integration of molecular approaches into the study of domestication history.

Until recently, archaeological research on plant domestication has been dominated by relatively few regions; among them are temperate North America, Western Europe, the Near East, and those parts of Mesoamerica and South America that gave rise to urbanism. Efforts are now underway to include the domestication histories of regions formerly marginalized, such as the humid tropics of Africa and the Americas, Southeast Asia, and the Pacific Islands. Integration of this new information highlights the global variability of human-plant interactions, leading to calls for each region to be understood on its "own terms" (Vrydaghs and Denham 2007: 11). Former colonies of Western nations are producing archaeologists whose worldviews are strongly influenced by awareness of indigenous perspectives on the plant world.

Future Directions

The past two decades have yielded a multitude of innovative techniques and approaches to plant domestication and cultivation in prehistory. The next two decades promise to be similarly productive, quite possibly in unanticipated ways. Based on current trends and gaps in knowledge, the following developments seem likely:

1. *Increased attention to the cognitive basis of decision-making and proximal mechanisms involved in plant use and management*. Archaeology has access to the material residues that document such decisions but lacks direct empirical evidence of the thought processes that motivated prehistoric people. However, cognitive science continues to yield insight into how the human mind works, in some cases documenting species-wide strategies such as rapid, intuitive decision-making and persistent biases. There is also much to be learned from studies of contemporary peoples who manage plants on a daily basis using traditional systems of knowledge. Their decisions are based both on socially learned information (culture) and their own experiences.
2. *Further exploration of biomolecules, especially aDNA, to document the history and spread of domesticated plants*. This research effort continues to expand to encompass more species and has moved beyond analysis of selectively neutral loci to the identification of loci known to regulate the phenotypic traits associated with domestication. Much continues to be learned from modern plant populations about their ancient predecessors, but aDNA will yield more opportunities for pinpointing key events in crop history. Judging by progress over the last decades, methods for analyzing aDNA will continue to be refined and improved in the years to come.
3. *More frequent application of models, particularly simulation models, to important questions about the process of domestication*. Modeling is a crucial analytic tool for understanding evolution in the case of prehistoric populations, which are imperfectly documented in the material record. Models permit the manipulation of numerous variables, such as population size, mutation rates, and rates of cultural transmission, under conditions that cannot be replicated in the real world. Their results enhance understanding of how variables are interrelated and provide a framework for interpretation of archaeological and genetic evidence (Allaby et al. 2008; Freeman et al. 2015; Gerbault et al. 2014; Ullah et al. 2015).
4. *Investigation of the domestication of nonfood plants*. Food plants, especially cereals, have been the focus of much domestication research because of their impact on human population

growth, social organization, mobility, and other sociocultural phenomena of interest to prehistorians. Fiber plants and fruit trees have received some attention, as have some psychoactive plants. Studies of major crops will continue, but innovations in residue analysis (for identification of lipids, alkaloids, and other biomolecules), fiber identification, and perhaps high-power microscopy of plant tissues will continue.

5. *Eventually evolutionary theory will be fully integrated with the study of plant domestication in prehistory.* Domestication is now widely accepted as an evolutionary process in which plants and humans both participate as coevolutionary partners, yet the processes that operate to bring about change on the human side of the equation remain poorly understood and undertheorized. Despite the discomfort of some researchers with the heuristic reductionism of behavioral ecology models, these models continue to yield insights into human decision-making. However, they represent only one strategy for advancing knowledge of plant domestication and agriculture in the past. Models of complex systems also have much potential, especially when combined with empirical testing, and both niche construction theory and developmental biology offer useful frameworks that will continue to guide research in the near future (Piperno et al. 2017).

Plant Micro-remains in Dental Calculus

Célia Boyadjian
Programa de Pós-Graduação em Arqueologia, Museu Nacional, Universidade Federal do Rio de Janeiro (UFRJ), Rio de Janeiro, Brazil

Introduction and Historical Background

Different types of analysis provide data on diet and subsistence patterns of ancient groups,

Plant Micro-remains in Dental Calculus, Fig. 1 Dental calculus deposits on teeth from an individual that was buried in the site Jabuticabeira II (2880 ± 75–1805 ± 65 BP), a shell mound from the southern coast of Brazil. (Photo: Célia Boyadjian)

contributing to the study of former ways of life. However, most of them are based on indirect evidence. The recovery of remains directly linked to diet is possible through the analysis of coprolites and gut contents, which are rare in many archaeological contexts. Luckily, another source of direct remains of food was discovered: the dental calculus (Fig. 1).

In contrast to coprolites, dental calculus is not rare. It is commonly found in teeth from humans and other species from different sites regardless of their location or context. The remains that are typically recovered from the dental calculus are botanical particles such as starch grains, phytoliths (biogenic silica particles), pollen, fibers, and tissue fragments, and they give us knowledge about plants that were eaten in the past. This is extremely valuable in contexts where plant material is rarely preserved.

But more than food remains, recent studies have shown that dental calculus can also store evidence from non-dietary activities, providing important information about habits and behavior. In fact, the analysis of calculus contents has proven to be very efficient and informative, which explains why this line of research has gained strength and relevance over the last decades.

First Studies

Before the development of the studies into its contents, dental calculus had already been used by bioanthropologists to investigate the oral health of past populations, since its growth is associated with the development of periodontal disease. In this approach, the deposits are macroscopically analyzed according to protocols established to evaluate calculus extent and severity (Dobney and Brothwell 1987).

The frequency and severity of calculus were also used to infer subsistence patterns of past human populations (Lieverse 1999). The problem with this type of analysis stems from the fact that different dietary patterns, as well as non-dietary factors, are associated with high levels of calculus formation (Lieverse 1999).

The first studies to promote calculus demineralization and microscopic analysis in search of direct evidence of diet were undertaken on animal samples (Armitage 1975; Dobney and Brothwell 1988; Middleton and Rovner 1994). The pioneer study on plant micro-remains from dental calculus dates back to the 1970s, when Armitage (1975) recovered phytoliths from samples from ungulates from British archaeological sites. About a decade later, Dobney and Brothwell (1988) were able to detect various types of plant, as well as animal remains, and preserved microbes in calculus of humans and domestic animals.

Just as in the animal studies, the first microbotanical studies on human calculus were also focused on the recovery of phytoliths (e.g., Lalueza Fox et al. 1996). But soon, the potential of the starch grain analysis was recognized (Boyadjian et al. 2007; Piperno and Dillehay 2008; Henry and Piperno 2008; Hardy et al. 2009). This was because this remnant is the direct evidence of the consumption of starchy food and enables the detection of plant items that are essential in the human diet such as roots and tubers, storage organs that generally do not preserve in archaeological contexts (Hardy et al. 2009).

Besides the aim of dietary reconstruction, during the 2000s many studies still had a more experimental character. Different research groups tested protocols and published exploratory studies, providing the general guidelines for calculus research

(e.g., Reinhard et al. 2001; Boyadjian et al. 2007; Henry and Piperno 2008; Hardy et al. 2009; Wesolowski et al. 2010).

After the publication of the pioneer studies, there were many advances in the field; however, it was only in the first decade of the new century that it began to expand more rapidly. In the last few years, the number of studies has grown significantly, and they included the analysis, not only of plant micro-remains but also of debris from different sources. The technique has been applied to human and other animal samples from the most diverse sites around the world, from contexts as old as 2 Myr (Henry et al. 2012) until the present day (Leonard et al. 2015). Some examples are presented in a later section of this chapter.

State of Knowledge and Current Debates

Formation and Composition

Dental calculus is formed by the mineralization of the dental plaque, a biofilm composed of microorganisms of the oral microbiome and proteins, which covers the surfaces of teeth and gums (Hillson 1996). The process of calculus formation is still not totally understood. However, it is known that the calculus accumulates during the whole life of the individual, in a continuous and incremental process, forming layers of deposition on the teeth (Hardy et al. 2012).

At first, the saliva and gingival crevicular fluids form an organic pellicle on the teeth surface, which becomes colonized by microorganisms, especially bacteria, forming the dental plaque (Hillson 1996; Lieverse 1999). Then, ions of calcium phosphate from these fluids precipitate in the dental plaque, mineralizing it, and forming the calculus deposits (Warinner et al. 2015). The calcium phosphate crystals occupy irregularities on the teeth surface as the plaque mineralizes, strongly attaching the calculus deposits to the teeth (Warinner et al. 2015). The layer of calculus formed has a rough surface, which favors microbial activity and, subsequently, the formation of plaque over it (Hardy et al. 2012). When the mineralization process of the inner layer of calculus is finished, dental plaque starts to form again and later mineralizes, forming another layer of calculus and so on (Hardy et al. 2012).

The dental calculus matrix is composed of organic and inorganic elements. The organic components include proteins, amino acids, carbohydrates, and lipids. The main inorganic components are calcium and phosphorus, while elements such as aluminum, magnesium, silicon, sodium, and manganese also appear in lower quantities (Hillson 1996; Jin and Yip 2002; Power et al. 2014). Hydroxyapatite, whitlockite, octacalcium phosphate, and brushite are the predominant crystalline forms of calcium phosphate in dental calculus (Hillson 1996; Lieverse 1999). The proportion of each crystal phase also varies in different deposits, which is related to the calculus maturation (Lieverse 1999). As the calculus matures, its crystallinity increases. Since brushite crystals tend to form first, they are more abundant in younger deposits, while mature deposits (up to 6 months) have more high-crystallinity phases of calcium phosphate crystals such as hydroxyapatite (Lieverse 1999; Jin and Yip 2002). Therefore, the more mature inner layers of calculus are, the more highly crystalized than the outer layers (Warinner et al. 2015).

The deposits are classified in two types: supragingival calculus, the deposits that form above the gum margin, on the tooth enamel; and subgingival calculus, formed below the gum margin on the tooth neck (Hardy et al. 2009). In spite of the similarities in the appearance and formation of both types of deposits, they have different structures and inorganic compositions, which are possibly related to the different microenvironments where they are formed and to the dental plaque associated with each type of deposit (Lieverse 1999). The supragingival calculus tends to accumulate on the buccal surface of molars and premolars from the maxilla and on the lingual surfaces of anterior teeth from the mandible, close to the location of the salivary ducts, while there appears to be no difference in the distribution of subgingival calculus (Lieverse 1999; Jin and Yip 2002).

The calculus composition is different among species. In fact, even among individuals from the same species, or the same group, there are not

only differences in the composition but also in the rate of calculus formation and extent of the deposits. That is because the calculus formation is influenced by multiple factors like the oral pH, salivary flow, genetic predisposition, age, oral hygiene, and masticatory disorders (Lieverse 1999). Diet is also one of the factors that is associated with the calculus formation, although how much it can affect it is not totally clear. For example, a protein-rich diet can increase the alkalinity of the oral pH, increasing the precipitation of the minerals of the oral fluid, thus promoting the calculus accumulation, but at the same time, a diet rich in carbohydrates promotes the plaque accumulation, indirectly influencing the calculus formation (Hillson 1996; Lieverse 1999).

During the feeding process, microscopic remains of the chewed plants are retained in the dental plaque. While the plaque mineralizes and the calculus deposits are formed, they get trapped in its matrix. Since the calculus matrix is very resistant, these particles are protected from diagenesis and can be recovered and analyzed even after thousands of years. In fact, while dentine and cementum suffer degradation after death, ancient calculus samples seem to suffer little alteration (Warinner et al. 2015). As many of these particles escape the action of digestive enzymes and microorganisms, hence preserving their features and morphology and thus allowing taxonomic determination, it is possible to identify the plants that were consumed.

Activities other than feeding can also leave remains in the dental calculus. It can happen, for example, when the teeth are used as tools to hold, scrape, soften, and break plant material to produce artifacts such as baskets, nets, tapestry, and so on (Hardy et al. 2009; Boyadjian et al. 2016; Radini et al. 2017). But besides plant remains, fragments of animal tissues and hair, sponge spicules, diatoms, parasites, bacteria from the oral microbiome, and others can also become preserved and identified (Fig. 2). Potentially, everything that was inside somebody's mouth can be detected through its traces left in the dental calculus.

Thus, the analysis of the dental calculus content is a powerful tool for dietary reconstruction but also provides data for environmental studies and for the investigation of other aspects of life in the past, including evidence of medicinal use of plants, artifact production, food preparation processes, inhaled or unconsciously ingested

material, sources of potable water and aquatic resources, and health conditions.

Processing and Analysis

There are various protocols for the microscopic analysis of dental calculus contents. Most of them consist of the decalcification of the calculus matrix in order to release the trapped microparticles and permit their proper visualization. However, there is still no consensus on which protocol is the most appropriate because of (a) differences in the nature of the samples themselves, which makes necessary the adaptation of the protocols for each site, and (b) the remaining gaps in our understanding about calculus formation and the incorporation and preservation of the microparticles.

Thus, different methods have been tested to evaluate, for example, what type of information this material is able to provide or the potential damage each technique has on the micro-remains or the teeth. Examples of methodological tests can be found in the literature (Lalueza Fox et al. 1996; Boyadjian et al. 2007; Henry and Piperno 2008; Hardy et al. 2009; Wesolowski et al. 2010; Power et al. 2014, 2015b; Leonard et al. 2015; Tromp et al. 2017).

Before being extracted from the teeth, the dental calculus deposits should be photographed, and its characteristics (such as extent and location) should be registered according to established methods (Dobney and Brothwell 1987) to prevent loss of information that can be important for bioanthropological studies.

Then, with sterilized curettes, calculus fragments are detached carefully in order to not damage the teeth surface. The fragments are collected, weighed, and transferred to sterile microcentrifuge tubes where they will be decalcified. Hydrochloric acid (HCl) is most commonly used for decalcification, but other chemicals such as EDTA (as described below) have also been tested.

Depending on the type and concentration of the solution used, the decalcification can take from a few minutes to days. When completed, the samples are centrifuged, and the supernatant is discarded. Distilled or ultrapure water is added, the samples are homogenized and centrifuged, the supernatant is discarded again, and these steps are repeated a few more times before the pellet is used to mount the microscope slides. Ethylic or isopropyl alcohol can be added to the precipitate so the samples can be stored before the analysis (Boyadjian et al. 2007; Wesolowski et al. 2010; Tromp and Dudgeon 2015). The final residue can also be dried at 40 °C to be weighed before mounting (Madella et al. 2014). Details on different protocols and steps not described here can be found elsewhere (Lalueza Fox et al. 1996; Henry and Piperno 2008; Hardy et al. 2012, 2017; Afonso-Vargas et al. 2015; Leonard et al. 2015; Weber and Price 2015; Power et al. 2015b).

When the calculus deposits are too faint to be mechanically detached, an alternative technique called "dental wash" was proposed (Boyadjian et al. 2007). It consists of the immersion of the tooth crowns into a weak solution of HCl (4%) to dissolve the remaining calculus, releasing the microparticles. Although the method efficiently recovers micro-remains and provides similar results to those obtained with the regular treatment, it can severely damage the teeth and should be avoided (Boyadjian et al. 2007).

There has also been concern about undesired effects of the HCl. It is suspected that it could damage remains like starch grains, which are a priori more fragile, preventing their identification and even detection. Considering this, methods that are supposedly less destructive have also been proposed. Some of them even exclude the decalcification. The calculus can be scraped off of the teeth directly onto the slide and mounted to be analyzed immediately (Piperno and Dillehay 2008). Alternatively, calculus fragments can be transferred to microtubes with glycerol and gently macerated (Power et al. 2014, 2015a). These methods can be challenging, however, because dense calculus fragments can prevent the proper visualization of some of the micro-remains (they can "hide" inside or behind chunks of calculus matrix). Also, when mounting the samples, large calculus particles can make it difficult to correctly place the coverslip on the slide.

More recently, the use of EDTA was proposed as an alternative to HCl for the calculus decalcification (Tromp et al. 2017), based on a protocol established for aDNA extraction (Warinner et al.

2015). The calculus fragments are immersed in a solution of EDTA 0.5 M and are left overnight in a rotator/nutator. If the decalcification is not efficient after that, the remaining big fragments should be crushed with a micro-pestle before proceeding. The samples are then left in the EDTA solution and periodically checked until decalcified. Similarly to the HCl protocols, the samples are then centrifuged, the supernatant is removed, and the pellet is rinsed with ultrapure water. This process is repeated three times.

Tromp and colleagues (2017) have tested both solutions with calculus samples equally subdivided and have recovered more micro-remains, especially starch, from the ones treated with EDTA. They suggested that the higher efficiency of the EDTA could be related to a gentler decalcification when compared to the HCl, what would be less damaging for the microparticles. However, there are studies that tested the effects of native (modern and archaeological) starch grains exposure to a low concentration of HCl at room temperature and did not find damage (Henry and Piperno 2008; Leonard et al. 2015). In any case, the authors argue that more tests are required to better compare both methods, but they suggest the use of EDTA when the microscopic analysis is associated with genomic and proteomic analysis (Tromp et al. 2017).

After the processing, the final solution obtained from each calculus sample proceeds to a typical micro-botanical analysis. Microscope slides are mounted with an aliquot of the solution and a drop of a mounting medium that permits the rotation of the micro-remains, which is essential for their description and identification. Glycerol is commonly used because its refractive index allows for the observation, in the same slide, of different types of microparticles. The amount of solution and glycerol mounted on each slide varies depending on the protocol and the amount of solution obtained after the extraction, but they should be transferred to the slides preferably with a micropipette for more precision.

The material mounted is covered with a glass coverslip, and its edges are sealed (usually with nail polish) to avoid dehydration. The slide is then analyzed with a transmitted light microscope equipped with polarized filters because the birefringence is an important feature of some particles, especially starch grains. It is scanned under 200x magnification to detect the micro-remains, which are then documented under 400x or 630x magnification for description, identification, and counting. Microparticles are described according to international codes (Madella et al. 2005; ICSN 2011) and classified into morphotypes based on shared morphometric attributes. The types observed are compared with micro-remains from reference collections of modern and/or archaeological plants securely identified and pictures and descriptions available on published literature. Identification keys and classification systems of microparticles from the studied region are consulted when available. Whenever possible, the micro-remains are assigned to plant part and taxon (species, genus, tribe, or, at least, family).

It is also possible to use scanning electron microscopy (SEM) instead of optical microscopy (OM) to analyze the dental calculus contents. Some studies combined both.

The preparation of each sample for the SEM usually consists of mounting on a stub followed by coating with gold or carbon "to prevent surface charging by the electron beam" (Power et al. 2014). Before preparing the samples, some research groups also perform the decalcification of the calculus fragments. Details on the SEM analysis of calculus can be obtained in the literature (Dobney and Brothwell 1988; Lalueza Fox et al. 1996; Dudgeon and Tromp 2012; Power et al. 2014, 2015a; Tromp and Dudgeon 2015).

Compared to the OM, the SEM has a higher depth of view and is particularly useful for the examinations of particles like phytoliths or diatoms, where the details of the surface are important (Dudgeon and Tromp 2012). These remains, unlike starch grains, do not require the examination of internal diagnostic features for classification and identification. On the other hand, to detect starch grains trapped in calculus, the use of SEM-EDX for elemental testing was proposed (Power et al. 2014). However, scanning electron microscopes are not always available; the analysis can be costly and time-consuming. For a more detailed discussion on the suitability of the SEM for the dental calculus

analysis, please see research by Dudgeon and Tromp (2012) and Power et al. (2014).

Contamination Considerations

The possibility of contamination of archaeological samples by particles from the modern environment, especially starches, is a matter of concern (e.g., Haslam 2004; Crowther et al. 2014). The mineralized matrix of the dental calculus deposits protects its contents; however, contamination of samples during their processing in the laboratory is possible. For this reason, from the calculus removal from teeth to the preparation of slides, all the steps of the protocol used should be performed in the cleanest conditions possible.

The calculus treatment should be performed in a controlled environment, ideally a positive-pressure laminar flow hood inside a clean room facility with sealed windows, controlled airflow, and restricted access. However, this type of lab is not always available. In any case, it is very important to thoroughly clean the lab surfaces and tools used and perform control tests periodically. The benches and tools can be cleaned with chemical solutions that are capable of destroying the contaminants, like sodium hydroxide (caustic soda). Non-disposable tools can also be autoclaved or boiled. Every item, from the soap used to clean tools and glassware, to the microscope slides, should be tested for contaminants. Protocols for the cleaning and detection of contaminants in the lab used for micro-botanical analysis can be found in the literature (e.g., Crowther et al. 2014; Henry et al. 2014; Power et al. 2015a, b).

The surface of the calculus deposits, and the teeth where they are attached, should ideally be cleaned before the removal of the samples. This prevents contamination by micro-remains not only from the environment but also from the sediment from the site, which can still be attached to the teeth. Thus, it is important to collect samples of sediment, either adjacent to the tooth or directly from the site, to perform comparative analysis (Middleton and Rovner 1994). New soft toothbrushes (one for each sample) and distilled or ultrapure water are used for the cleaning (Middleton and Rovner 1994). Some authors also apply a gentle chemical pre-treatment on the already detached calculus fragments to eliminate superficial contamination (Hardy et al. 2012; Tromp et al. 2017).

During the processing of each batch of calculus samples, it is advisable to include negative controls (Wesolowski et al. 2010; Tromp et al. 2017). They must be processed and analyzed the same way the calculus fragments are, to verify possible contaminants that can enter the experimental samples during any step of the protocol.

Key Dental Calculus Studies

There are many interesting studies published on the microscopic analysis of dental calculus. Some examples are presented below.

Early Hominins

Some of the key researches on plant micro-remains from calculus were applied to the study of early hominins. They were undertaken to investigate the feeding ecology of *A. sediba*, a fossil from South Africa dated from ca. 2 Myr ago (Henry et al. 2012) and the diet and habits of one of the oldest (*ca* 1.2 Myr) hominins from Europe (Hardy et al. 2017). However, most were carried out with Neanderthals (e.g., Henry et al. 2011, 2014; Hardy et al. 2012). Some of these studies also combined the examination of calculus micro-remains with other types of analysis.

Henry and collaborators (2011) were the first group to publish a study of this nature with Neanderthals. They analyzed samples from caves from Iraq and Belgium and were able to recover phytoliths and an abundance of starch grains as direct evidence of diet. Their data demonstrated that those Neanderthals probably consumed a variety of plant foods, including items that are common in recent diets and items that are costly to exploit, like grass seeds, contradicting the idea that they were mainly "meat-eaters" with a restricted "menu" (Henry et al. 2011). They also reported starch with signs of damaging from cooking, showing that those groups also processed some of the plants they ate, increasing their nutritional quality. Thus, the authors argue that the dietary adaptations that were believed to have been developed by early modern humans in

fact already existed by the Late Middle Paleolithic.

Later the authors expanded their analysis comparing the data obtained (starch and phytoliths) from calculus and lithic instruments from 30 populations of Neanderthals and early modern humans from Europe, Africa, and the Near East (Henry et al. 2014). They examined 209 samples and performed quantitative and qualitative analysis in the biggest large-scale sampling strategy to date for this type of study. Their data indicates that "both species consumed a similarly wide array of plant foods" and the dietary ecology of Neanderthals was more complex than previously thought (Henry et al. 2014).

Another example is the research carried out on samples from Neanderthals from El Sidrón Cave, Spain (Hardy et al. 2012). This research was the first to perform the analysis of chemical compounds from dental calculus and also to combine it with the morphological examination of microparticles (using SEM and OM techniques). From the microscopic analysis, they obtained mostly starches (only one phytolith), indicating the consumption of starchy food. From the chemical compounds of some samples, they obtained evidence of the ingestion of cooked carbohydrates and of wood-fire smoke inhalation. This, together with the starches with sings of cooking that were found, was interpreted as food preparation with fire and repeatedly exposure to wood smoke. The chemical compounds also indicated the ingestion of non-nutritional plants (such as yarrow and chamomile), which was interpreted as being deliberately consumed as medicine (Hardy et al. 2012).

Food Production

Going further on dietary investigation, some studies have also discussed the subsistence patterns of pre-agrarian populations, the early use of major food crops, and the beginnings of food production in different regions of the world through data from dental calculus (e.g., Piperno and Dillehay 2008; Mickleburgh and Pagan-Jimenez 2012; Chinique de Armas et al. 2015; Madella et al. 2014).

Piperno and Dillehay (2008), for example, analyzed micro-remains from dental calculus from sites of the Ñanchoc Valley, Northern Peru. Their data indicated that, by approximately 8000 year BP, there were effective food production systems in the region and the diet was diverse and stable and already included important cultivated plants from the late Andean agriculture (squash, peanuts, beans, and inga). Intriguingly, they did not find phytoliths in their samples, just starch grains. This was attributed to "the fact that the plants evidenced on the teeth and many others that were potentially available in the study region do not produce phytoliths in their edible parts" (Piperno and Dillehay 2008).

In Brazil, Wesolowski et al. (2010) published a very detailed methodological study, the first with a larger sample size compared to what was typically analyzed at the time. They worked with samples from archaeological sites known as *sambaquis*, the Brazilian shell mounds, from different periods from the Holocene and found an abundance of micro-remains, mostly starch and phytoliths, but also micro-charcoal and mineral particles. They noticed that starch was the most abundant microparticle and was present in all samples. Some of the grains were also damaged which, together with the presence of micro-charcoal, was suggested as evidence of food preparation practices. However, they did not discard the possibility that the charcoal fragments were the result of contamination.

It is currently accepted that the subsistence of the *sambaqui* groups was heavily dependent on fish (and complemented with shellfish), and until recently, the information about plant use was very limited. This research, together with data from the study of Boyadjian et al. (2016), has provided essential direct evidence of the plants that were eaten, and possibly cultivated, by Brazilian shell mound builders, reinforcing the results of the pioneer anthracological studies by Scheel-Ybert that demonstrated the importance of plants in their daily life (see chapter "▶ Landscape and Plants Use in Brazilian Shell Mounds" for a detailed discussion on this subject).

In another example from the Neotropics, Mickleburgh and Pagan-Jimenez (2012) studied starchy food consumption in the pre-Columbian insular Caribbean. They were interested in

investigating the use of cultigens by precontact groups in the region, and their data confirmed the importance of maize for these populations. Additionally, the authors of the study found starch grains with signs of damage and argued that maize was consumed ground and baked as bread. Other plants were also identified, indicating that the diet was broad, with a variety of root crops as staples, and varied locally (Mickleburgh and Pagan-Jimenez 2012).

Outside of the Americas, Madella and colleagues (2014) investigated the use of plants by Neolithic communities from the Nile Valley whose economy was supposedly pastoral. The knowledge about the processes related to the transition to agriculture in the region was restricted because of the scarcity of direct data on plant macro-remains. However, the authors reported starch grains and phytoliths from the calculus samples analyzed from two cemeteries from Central and Northern Sudan. They also recovered phytoliths from pillow-like structures that were found behind the skull inside the graves.

Their data indicated that these groups were consuming Near East domestic cereals such as wheat/barley, millets, and wild local grasses, legumes, and non-identified starchy plants, including probably local tubers. They also systematically used grass inflorescences as grave goods. Despite being considered mainly pastoralists, theses societies exploited a variety of plant resources and cultivated cereal crops. The evidence also indicates that Near East domestic cereals were available in Northern Africa earlier than previously thought, confirming "an earlier spread of the Near East type of agriculture towards the South" (Madella et al. 2014).

Dental calculus studies focused on diet, and investigation of plant-based subsistence strategies and development of agriculture were also undertaken on Asian archaeological sites. Tao and colleagues (2015), for example, carried out this type of research on Gouwan, a site in the Yellow River Valley, China, also from the Neolithic (Yangshao period: 5000–3000 BC). The data from the starch grains recovered by them indicated that a variety of plants, including not only domestic cereals but also wild gathered plants, were consumed. Apart from millet and possibly rice, they recovered starch from roots and tubers, wild grasses from the wheat tribe, acorns, and job's tears, plants that were not present among the macro-botanical remains recovered in previous studies.

In the middle Yellow River basin, the economy pattern was millet agriculture (Tao et al. 2015). In fact, the evidence of millet and rice from the calculus samples and from the macro-remains record points to cereal cultivation in Gouwan site. However, the low frequency and density of charred cereal remains and previous data from stable isotopes, together with the presence of micro-remains from gathered plants from the study of Tao et al. (2015), suggest that millet agriculture was not the basis of the economy in Gouwan. The authors argue that the role of gathered plants during the Yangshao period, when the agriculture was already developing, should be reconsidered.

Animals and Modern Samples

Recently, interest in the analysis of plant remains from ancient nonhuman animal calculus was renewed, but the researches are not only focused on phytoliths and have a different approach from the pioneer studies (e.g., Power et al. 2015b; Weber and Price 2015).

For example, Weber and Price (2015) show the potential that dental calculus analysis has on the understanding of past human-animal interaction. They investigated ancient pig husbandry through the analysis of dietary remains from samples from Mesopotamian sites (from tenth to third Millennium BC), the region where this animal was first domesticated. The data from starch grains and phytoliths showed that the pigs were eating domestic cereals, grasses, wild tubers, and acorns. They also reported the presence of damaged cereal starch in the samples of the sixth millennium pigs and some wild boars, indicating they were eating processed and cooked food from household refuse. This data is evidence of a dietary shift of pigs at this period and of close association between wild boars and human settlements in the Neolithic (Weber and Price 2015).

Lately, modern samples from both humans and other animals were also included in the studies of

plant micro-remains from calculus. The aim of these studies was to examine samples obtained from groups with a well-documented diet, to verify how precisely the food consumed is represented by these remains.

Leonard and colleagues (2015) analyzed samples from a living population of forager-horticulturalists from Namibia and were the first group to test how well the phytoliths and starch grains from calculus can reflect the plant foods eaten. They found out that, while the micro-remains can give a good idea of the plant consumption of the population as a whole, they do not precisely represent the diet of each individual. They noticed a lot of individual variation in the plants represented by the micro-remains, which they believe is related to differences among individuals in the calculus formation and, thus, in the preservation of micro-remains.

The authors also argue that the analysis of micro-remains from dental calculus works well for identifying specific plant *taxa* in the diet but is not adequate for investigating the intensity of consumption. For example, while maize was intensively consumed by the population, maize starch was present in only 30% of samples (Leonard et al. 2015). In the case of maize, they believe it could be partially explained by food processing which would have heavily damaged the starch grains, reducing their abundance and thus its presence in the calculus record.

In another research, microparticles from dental calculus of modern chimpanzees were studied as a model for understanding diet and events of life history (Power et al. 2015b). The team aimed to investigate the capacity of calculus to capture diet composition by analyzing samples from individuals with a long-term behavior documentation (over 20 years of records).

The authors noticed that, in contrast to what was reported previously in some studies on human calculus, the phytoliths are abundant in the chimpanzee's samples. They attributed this to the differences in the diet of both species and the nature of the samples (they are modern and, supposedly, less affected by diagenesis). On the other hand, starch grains were underrepresented. According to their data, the micro-remains from dental calculus represent a "long-term dietary signal" and can provide interesting insights into diet, behavior, and life history. They also conclude that the phytolith abundance in the calculus reflects the dietary breadth of the chimpanzees, but the starch record is more uncertain.

Other Micro-remains

Besides microparticles from plants, the dental calculus deposits contain other types of debris from many different sources. These botanical and non-botanical remains can come from the food itself, but they can also be unconsciously ingested together with food and water. They can also become trapped in the calculus after being inhaled or during different activities such as oral hygiene and the use of the teeth as tools. A few examples of non-botanical remains that can be found in calculus are presented below, but for more details on non-dietary debris, see Radini et al. 2017.

Interested in the subsistence practices of the ancient Rapanui, Dudgeon and Tromp (2012) studied micro-remains from calculus of skeletons (dated between AD 1330 and 1900) from different regions of the Easter Island. They focused on the biogenic silica, reporting a huge amount of phytoliths and diatoms, something unusual for most studies (Dudgeon and Tromp 2012). Since they analyzed a large sample (114 in total), they were able to statistically test the micro-remains' distribution by age, sex, dental element, and geographic region of the skeletons but did not find significant differences by age, sex, and dental element. The proportion of diatoms, however, was significantly higher in the samples from the southern region of the island, and the authors believe it could be related to the access to different sources of drinking water.

Almost 95% of the phytoliths found were palm phytoliths. However, the presence of so many palm remnants in the calculus of the analyzed individuals could not be successfully explained mainly because it seems that the species of palm native to the island was nearly extinct when they were alive (Dudgeon and Tromp 2012). To understand this result, they published a second study, this time also interested in starch grains (Tromp

and Dudgeon 2015). The starch grains recovered were consistent with sweet potato, and palm starch was not found. The authors argue that the skin of sweet potato can incorporate phytoliths available in the soil during the roots development. So, the phytoliths detected in the calculus were interpreted as remains left by the consumption, not of palms, but of sweet potato that grew in the soil where the extinct native palms had previously grown.

Their research is interesting because it was one of the few calculus studies to use a large-scale sampling strategy. Also, although other studies had previously reported diatoms in dental calculus (e.g., Middleton and Rovner 1994; Boyadjian et al. 2007), they were the first to propose interpretations based on this class of remain. Later, Boyadjian and colleagues (2016) were the first to perform the taxonomic identification of diatoms from calculus. They identified five types of diatoms found in samples from a Brazilian coastal shell mound, and through this finding, they were able to support the hypothesis that the aquatic resources consumed by the group was obtained in the paleolagoon near the site, not in the open sea.

Fungal spores are another example of non-botanical remains that can be recovered from dental calculus. During the 2000s, Afonso-Vargas performed methodological tests and applied the developed protocols on calculus samples from precontact and historical sites from the Canary Islands (Afonso-Vargas et al. 2015). Interestingly, besides plant remains, an abundance of fungal spores were found in samples from two individuals from the historical site.

Recently, his findings were reconsidered aiming for the identification of the spores, and the data indicated that they came from a parasitic corn fungus (Afonso-Vargas et al. 2015). Comparing the results obtained from the calculus with the data from sediment samples from the site where the remains were buried, the hypothesis that the spores were result of contamination was ruled out. Additionally, the identification of the spores, together with the data from starch and phytoliths, enabled them to conclude that the consumption of corn increased during the eighteenth century, bringing dietary changes to the population of the island.

Fungal remains were also reported in a microscopic study of calculus from El Mirón Cave, a site from the Magdalenian period in Cantabria, Spain (Power et al. 2015a). The analysis indicated that they originated from species that produce mushrooms and could represent its intentional ingestion (Power et al. 2015a). In fact, the authors noticed a much more diverse micro-remains assemblage in their calculus samples than usually reported for other contexts, including fungi, plant (starch, phytoliths, and unsilicified fragments), animal, and mineral remains. Other studies show that the Cantabrian Magdalenian diet depended on animal foods, but these findings reveal other components of the dietary spectrum in El Mirón (Power et al. 2015a). According to the authors, this points to a mixed subsistence pattern, where the consumption of animal resources was complemented by various plant foods (including seeds and underground storage organs) and potentially mushrooms.

Future Directions

In addition to the microscopic analysis, other techniques have been recently developed for accessing the dental calculus contents: stable isotope studies, analysis of chemical compounds, and studies of proteins and DNA. Although the first one is still controversial (Salazar-García et al. 2014), the other techniques have been applied to different contexts and have brought very interesting results about diet, food processing, medicinal use of plants, evolution of the oral microbiome, ancestry, health, and behavior (e.g., Hardy et al. 2012; Warinner et al. 2014, 2015; Weyrich et al. 2015). Combined with the traditional methods, they are opening an exciting new line of research in archaeology.

The first studies undertaken with these new techniques were published at the beginning of the present decade, and they are very rapidly expanding. Hardy and collaborators (2012) were the first group to explore the use of thermal desorption-gas chromatography-mass spectrometry (TD-GC-MS) and pyrolysis-gas chromatography-mass spectrometry (Py-GC-MS) to characterize organic

compounds from dental calculus samples identifying the sources of these compounds. As already mentioned in a previous section of this chapter, with this technique they obtained very interesting results about Neanderthal diets and habits, including the first direct evidence of the use of medicinal plants (Hardy et al. 2012).

Another example is the research by Buckley and colleagues (2014). Interested in investigating the use of plants by pre-agrarian and agrarian groups and the ecological knowledge in prehistoric times, they carried out a combined study of chemical compounds and micro-remains from calculus samples from Al Khiday, a Central Sudanese site. Since this is a multi-period site in the Sahara region, they were also able to verify the long-term preservation of calculus contents in an extreme climate but did not find differences.

They were not able to identify most of the starch grains found. However, evidence from the chemical analysis indicated that *Cyperus rotundus*, a carbohydrate-rich plant that can also be used as medicine, was consumed during the pre-agricultural and agricultural periods of the site. The authors show that, despite being currently considered one of the world's worst weeds, it was an important food item for different cultures around the world and was also broadly used for non-nutritional purposes. Also, since this plant has the ability to inhibit *S. mutans*, the unexpected low caries prevalence reported during the agricultural period could be explained by its use (Buckley et al. 2014). They also find evidence of smoke inhalation in all the samples analyzed for chemical compounds, indicating the use of fire during all periods of occupation of the site. Cooking by roasting and heating in water were also proposed. Finally, fibers, possibly from the stem of monocots, were also found, indicating that the groups from Al Khiday could have used the teeth as tools to process plant material.

The analysis of ancient DNA (aDNA) and proteins from dental calculus has been applied only during the last few years. It has already provided remarkable data about diet and health, but there are still unexplored applications with the potential to bring outstanding results for archaeology and paleoanthropology (Weyrich et al. 2015).

Warinner and collaborators (2014) published one of the first studies of this nature. They carried out shotgun DNA sequencing on samples from individuals with severe periodontal disease from a medieval site from Germany and modern samples of individuals with non-dental history. They were able to characterize 40 opportunistic pathogens involved in oral pathologies as well as systemic diseases and also detected antibiotic-resistant genes, showing that they were present in the human microbiome before the use of these medicines. They also reconstructed the genome of an important periodontal pathogen and showed that the "red complex pathogens" were already associated with the periodontal disease since the Middle Ages.

The authors of the research also obtained biomolecular evidence of food resources and validated their findings with other paleodietary studies including micro-remain analysis. They detected boar/pig, wheat, and crucifer, and from the modern samples, they identified a protein from milk. The micro-remain analysis revealed fragments of animal tissue, plant fibers, unidentified phytoliths from monocots, and starch grains from the same taxonomic group as the wheat and from the Fabaceae family. These results show that both methods can be used together to complement dietary data from the same samples.

Final Considerations

The studies described here demonstrate how valuable the dental calculus deposits are. They show how the analysis of its contents can provide interesting insights into different aspects of life in the past, like diet, habits, behavior, health, and technology.

This line of research has particular importance in archaeological contexts where information about plant use is absent or incomplete. Dental calculus provides precious data about sites from which archaeobotanical remains have not been recovered and new excavations are no longer possible, reinforcing the need for optimal osteological material curation in museums. Additionally, the dental calculus analysis has shed light in the

role of plants in the life of early hominins and pre-agrarian populations. It has provided unequivocal evidence of the use and consumption of plants by groups that were previously considered mainly "meat-eaters" (e.g., Henry et al. 2011; Power et al. 2015a; Boyadjian et al. 2016). Apart from diet, the analysis of micro-remains from calculus can reveal evidence of other activities such as food preparation, oral hygiene, and use of the teeth as tools (Radini et al. 2017). It can also reflect the unintentional ingestion of debris from various sources and provides data that can help us understand human-animal interactions (Weber and Price 2015; Radini et al. 2017). Last, but not least, since the micro-remains are protected by the mineralized layers of calculus, it is one of the safest and most reliable sources of information (Power et al. 2014; Hardy et al. 2009). This is firstly because even particles that are organic and normally fragile, like starch grains, can be protected and preserved inside these deposits for thousands of years. But also, since these particles are encapsulated in the calculus matrix, if the samples are processed in controlled conditions in a clean laboratory, the chance of modern contamination is low.

Of course, we have to take into account that, as with any other technique, it has its limitations. For example, the studies with modern samples demonstrated that starch grains and phytoliths from calculus are not precise indicators of the dietary breadth at the individual level, although it is possible to estimate the range of plants in the diet of the population (Leonard et al. 2015; Power et al. 2015b). Also, the dietary reconstruction based solely in phytoliths and starch grains from calculus is limited because these remains are only partially representative (Mickleburgh and Pagan-Jimenez 2012; Leonard et al. 2015; Power et al. 2015b). Plants that do not produce starch and phytoliths will be invisible in the calculus record through this kind of analysis. Even the plants that produce these microparticles are not necessarily represented in the calculus deposits. For example, plants that are intensively consumed but have a low starch content, or plants that are highly processed, causing significant degradation to the starches, might not be represented (Leonard et al. 2015). Thus, it is also problematic to predict the frequency of plant consumption.

In order to have an optimal picture of diet, health and way of life, interdisciplinary studies must be performed. The analysis of micro-remains should be combined with the new techniques developed for the analysis of chemical compounds and biomolecular markers from calculus, as well as with analysis of dental wear, stable isotopes, dental and paleopathologies, and coprolites.

Plant Processing Technologies in Archaeology

Andrew S. Fairbairn
School of Social Science, The University of Queensland, Brisbane, QLD, Australia

Introduction

Agriculturally produced plant seeds, tubers, and stems form the core of food systems for the vast majority of the world's population. Today, as in the past, effective use and consumption of these foods relies on processing technologies. Ever improving archaeological science techniques and improved collection strategies from archaeological sites are greatly increasing the temporal and geographical range of material evidence for past plant processing technologies. A wider frame of ethnographic and experimental reference is also improving the ability of researchers to interpret those traces. The key role of processing technologies in the long-term development of agricultural systems and in the domestication process itself is now well established, and higher-quality evidence from Paleolithic sites is now demonstrating the preagricultural presence of plant food processing in several regions over at least the last

30,000–50,000 years. Evidence now suggests that while processing is important for the evolution and adoption of domesticates, specific technological advances in processing were not the key triggers of domestication itself.

Definition

Plant food processing refers to a wide range of activities that ultimately have one aim: to extract edible foodstuffs from the inedible. Most plant tissues, with the exception of some soft fruits, are not edible or provide at best meager food value to human digestive systems without some form of processing. This includes a large number of foods that are routinely eaten today and are the focus of agricultural production systems around the world, including the edible grains, legumes, and many tubers. Without processing grains pass through the digestive system largely undigested; while without cooking, grinding, or leeching, many forms of legumes (e.g., grass pea (*Lathyrus sativus*) and chickpea (*Cicer arietinum*)) and some tubers (e.g., bitter cassava (*Manihot esculenta*)) are lethal. Inedibility results from a number of protective features of plant physiology and chemistry, in part prompted by evolutionary pressures from potential predators, including humans (Stahl 1984; Jones 2009). Most directly, plants may encase edible parts, such as seeds, in some form of protective coating, such as nutshells or grass-seed husks (chaff), which deter predation. In other cases the deterrent may be chemical compounds, ranging from relatively benign chemicals that reduce digestibility or cause a bitter taste to life-threatening compounds such as the arsenic-containing amygdalins of wild almonds, which poison the consumer (Martinoli and Jacomet 2004). Also of relevance are fibrous structures in plant leaves and stems which may hinder the mastication and digestion of otherwise nutritious plant foods.

While plants are relatively easy to locate and harvest compared to hunted animals, these protective features provide a series of challenges which must be overcome if plants are to make a contribution to the human diet. The solutions require the investment of significant time, energy, and equipment in a wide range of technological responses to the challenges of plant inedibility; they include a range of implements and techniques in many cases forming elements of quite complex multiple-step processing sequences (Hillman 1981; Jones 2009). Harvesting may include simple collection of plant resources from the ground, or more involved use of harvesting devices, such as sickles and digging sticks. Releasing the edible foodstuffs from nutshells, seed coats, husks, or fibers may involve pounding, cutting, or grinding combined with winnowing, sieving, and soaking. Detoxifying foods of chemical compounds may include pounding, leeching toxins with water, grinding, and heating, which may also be employed to break up larger plant structures – such as grass seeds – into smaller more digestible particles, such as grits and flour. Perhaps the best-studied multiple-step processing sequence is that of the Old World cereal crops, which in ancient glume wheat species (e.g., einkorn (*Triticum monococcum*) and emmer (*Triticum dicoccum*)) includes harvesting, threshing to separate the cereal spikelets from the straw, winnowing to remove the chaff, pounding to release the grains from the chaff, and various stages of sieving and hand sorting to remove the weed seeds, straw nodes, and remaining chaff before the grain is milled and eaten. This process can be undertaken using a range of tools and spaces and results in the production of a range of products and by-products which may be identified in archaeobotanical assemblages.

These processing techniques are found in many plant procurement systems, whether using wild resources or domesticates. They leave a range of potential archaeological traces, including the tools used to process the plants, such as grinders, pounders and blades, processing installations and even the residues of the processed plants themselves. The scale and organization of plant processing varies in different societies, depending on their economic emphasis and structure, as reflected in the number, size, and organization of processing facilities. Settlement remains from small-scale societies commonly preserve the remains of grinding stones distributed through

dwellings or in communal areas, such as threshing floors, while urban societies may see the development of specialist processing facilities for production of food (e.g., centralized bakeries as seen in Classical cities) or production of foodstuffs as commodities. Archaeological study of food processing thus illuminates not only nutrition but also the socioeconomic aspects of food production. Only in recent years have archaeologists fully realized the potential of this material archive to allow the study of plant processing systems. Of particular importance in studying plant processing technologies has been the development of plant residue analysis, especially of starches, which has broadened the range of contexts from which plant remains are recovered and greatly expanded the geographical range of those studies, as has the development of high-powered microscopy of tuber and other macrofossil remains.

Key Issues/Current Debates/Future Directions/Examples

It is fair to say that recent decades have seen revolutionary advances in the archaeological *identification of processing technologies and sequences* which have caused major reevaluations of the economic conditions and food systems of past societies. While at one time the function of processing-related artifacts – such as pots, stone tools, and grinders – could only be inferred from sometimes contradictory ethnographic analogues, residue and use-wear analysis are now providing increasingly accurate and widespread tools to identify directly traces of past artifact function. Residue analysis identifies the traces of past use of artifacts and installations through identification of plant, animal, and mineral substances adhering to or absorbed into their surfaces, including starches, phytoliths, and chemical biomarkers. Analysis of starch residues and phytoliths has been particularly effective in identifying plant-related processing tools. In the Asia-Pacific region, such studies have not only demonstrated tuber and seed exploitation 40,000–50,000 years ago (Barton 2005; Summerhayes et al. 2010) – among the earliest in the world – but have confirmed the use of tubers in the independently evolved early agricultural systems of highland New Guinea (Denham et al. 2003) and the evolution of intensive nut exploitation in Holocene Australia (Cosgrove et al. 2007). These examples serve to illustrate the fact that archaeological understandings of plant use in the tropical zone have been disproportionately improved by starch and residue research – a fact that has perhaps gone relatively unnoticed in the traditional Old World centers of archaeobotanical research – in great part because food production systems in the wet tropics are often focused on otherwise poorly preserved tuber, leaf, and fruit crops. Another region which has undergone this revolution is tropical America, which now has a rapidly developing prehistory of crop use supported by microfossil research extending into the earlier Holocene (e.g., Perry et al. 2007).

Use-wear analysis, which aims to identify traces of use via the abrasion patterns found on tools, is a particularly promising area of research for understanding past food technologies. It has been useful for identifying processing artifacts, including both stone blades and grinding stones, though difficulty still persists in unambiguously separating the wear traces from different activities (Goodale et al. 2010). Sickle wear – the glossy sheen on stone blades caused by cutting grasses, including cereals – has long been used as an indicator of cereal use at Natufian and early farming sites, though it is very difficult to separate the harvest of cereals from other grasses, such as reeds. Recent studies of Natufian sites have used experimental references to identify not only an increased focus on plant processing over time but also a great increase in the diversity of processing activities during this period.

Use-wear analysis is strongly dependent on *experimental archaeology* – in which ancient practices are replicated or reconstructed through a controlled series of steps – as a source of analogues. This approach has a long pedigree with pioneering studies by Jack Harlan first demonstrating the potential of wild cereals as a sustainable source of food in Southwest Asia. It also has been of great importance for understanding the techniques and effects of plant food processing

worldwide (see other references in this section). A particularly important set of harvesting experiments established that sickle harvesting positively encouraged the development of domestic traits in Old World cereal crops by selecting for non-shattering crop phenotypes and its introduction could lead to domestication in a few generations (Hillman and Davies 1990). This observation helped refocus archaeobotanical studies on how different crop processing practices could effect and even trigger the trajectories of domestication. Interestingly archaeobotanical studies have demonstrated domestication in seed crops to have actually taken millennia (for a detailed discussion, see Fuller 2007). Beyond Southwest Asia, recent research has used replicative experiments to help identify nut processing techniques from the fracture patterns on the remains of the nuts themselves as a means of testing earlier models of intensive plant exploitation (Asmussen 2010).

Experimental studies have commonly been used in combination with *ethnographic studies*, namely, accounts of actual food processing behavior in societies around the world. Such studies have been important for understanding both the range of food processing techniques and their ubiquity across the occupied continents in very different societies. As noted above, ethnographically informed models of crop processing sequences in Southwest Asia transformed the ability of archaeologists to understand how people processed plant foods in the past by providing the means to directly identify them in ancient datasets and understand some of the variations such processes cause in the archaeobotanical record, thus helping to refine interpretations of harvest and other activities. Such an approach demonstrated that the cultivation of low-return small-seeded grasses in North America may have been adopted as they could be processed in the winter when lack of other tasks meant the return was worthwhile (Gremillion 2004).

More importantly ethnographic and ethnohistorical studies have also extended our knowledge of how foragers utilize and process seeds and other plant resources and have contributed to the *reconceptualization of agricultural origins*. Of special interest are the accounts of foraging behavior in Indigenous Australia, the American northwest, and parts of the Americas, which have shown a close similarity between many "non-agricultural" plant harvesting and processing activities and those of agriculturalists (see papers in Denham et al. 2009a). For example, studies in Australasia demonstrate the relatively late focus on intensive seed and tree-nut exploitation – enabled by the grinding and detoxification of seeds and toxic species – in the case of the Atherton Tablelands within the last 2000 years (Cosgrove et al. 2007). It is increasingly clear that intensive use of seeds, tree nuts, and tubers, including the tending and even replanting of favored food-producing species, as well as storage, detoxification, and grinding, is undertaken by foragers. The distinction between a non-agriculturalist and an agriculturalist is often quite arbitrary and in many cases comes down to the presence or absence of morphologically domestic taxa. This insight is largely derived from work in the Americas, Australia, and parts of Africa and East Asia but has veracity for understanding the transition to sedentary farming lifeways in Southwest Asia and other classic agricultural hearths, where once simple binary transitions from forager to farmer can now be challenged on the basis of ever more detailed archaeological evidence (Zohary et al. 2012).

Within the *narrative of ancient agricultural origins and sedentism*, food processing technologies have a central role. To put it simply, the long-term sustenance of large groups of people living together in a restricted space – as we find in farming societies – in most cases outstrips the capacity of environments to provide it. Sedentary societies are prone to food shortages because they are unable or unwilling to adopt residential mobility as a means of overcoming shortages in foods caused by seasonal cycles of abundance or less predictable factors such as loss due to fire or pests. As noted above, processing techniques are a means of unlocking the nutrients in potential foods that may be available but otherwise unused to thereby increase the dietary potential and – in ecological terms – the effective carrying capacity of those environments. Processing of otherwise inaccessible foods lies at the core of seed-based agriculture in the Old World, China, and parts of the Americas

and Africa and when combined with storability accounts for their prevalence among societies in need of vegetable foods.

Extracting the nutritional value requires considerable energy expenditure in grinding or other forms of processing. The question must arise: why bother? For high-density populous societies such processing of seeds and other crops may be the only means of supplying core calories for people and their animals. For earlier societies, especially late foragers, the question is very pertinent. Recent archaeological research – in great part fuelled by the methods summarized above – has shown that increased reliance on plant processing as a subsistence strategy emerges in the later millennia of the Paleolithic era. We know that nut cracking predates the evolution of *Homo sapiens* – and may be an ancient ancestral behavior as chimpanzee populations also use this practice. However, use of complex processing and a wider range of resources, including tubers and toxic seeds, is seen in parts of Europe, Southeast Asia, and Sahul dating from 30,000 to 50,000 years ago (Barton 2005; Revedin et al. 2010; Summerhayes et al. 2010). In the higher latitudes during the cooler periods of the Pleistocene, the answer is not simply one of supplying base calories. Meat-focused diets can lead to nitrogen poisoning and a significant plant food dietary input (in most places 25%) is required to buffer the nitrogen input from meat (Jones 2009). In highly seasonal environments, nuts, fruits, seeds, and tubers provide highly abundant and widespread potential sources of such foods, as long as appropriate processing methods are applied. Once considered a late Pleistocene development as part of the preagricultural "broad-spectrum revolution," the exploitation of a wide range of plants may have been a key human adaptive strategy for many millennia and contributed to the successful colonization of the world by early human populations. Processing techniques and sequences in all their complexity and diversity were part of that adaptive range of skills and were fundamentally important in realizing the nutritional potential of exploitable plants in those regions.

Intensive use and eventual domestication of plant species seems to have emerged from this long tradition of plant exploitation in some regions, perhaps as a result of specialization in plant subsistence practices on a narrow range of exploitable resources (see Denham et al. 2009b). As greater evidence emerges of the antiquity and scope of plant food processing and the extended period of domestication itself becomes clear, it is less and less easy to identify processing activities as a trigger for the domestication process, though some new technologies may have increased the chances of domestication happening. Rather, processing activities allowed much greater effective use to be made of a wider range of plant foods, which perhaps empowered communities to experiment with and find plants that could provide the reliable, bulk sources of calories on which sedentary subsistence could be based and that eventually were domesticated and farmed. Processing technologies thus provided the means by which plant selection and domestication could become possible, but their development does explain neither why domestication itself happened nor why the cultivation of domesticates became the chosen means of exploiting plant species for many societies around the world.

Plantation Archaeology

James A. Delle
Kutztown University of Pennsylvania, Kutztown, PA, USA

Introduction

The post-Columbian expansion of European colonial interests into the Americas, Africa, Oceania, Indonesia, and Southeast Asia resulted in the development of a number of strategies both for the settlement of European colonials and for the exploitation of natural resources, both endemic and introduced. Among these strategies was the development of large-scale monocrop agricultural establishments that produced tropical and subtropical agricultural commodities for the European and colonial markets. By the early seventeenth century, these establishments became widely known in the English-speaking world as "plantations." Having used a variety of labor extraction strategies to produce a variety of crops, many plantations were abandoned, or their landscapes transformed, by the early twentieth century, resulting in a rich archaeological record that has been systematically explored since the early 1970s. The scope of plantation archaeology extends from the US South through

the Caribbean, the Atlantic and Indian Ocean islands, East Africa, and the Pacific.

Definition

Plantation archaeology is a somewhat difficult term to define, largely because the definition of "plantation" is itself somewhat ambiguous. In common practice, a plantation is a large-scale monocrop agricultural estate, generally worked by resident labor. However, the term "plantation" has historically been used to define vanguard colonial settlements, which may or may not focus on the production of agricultural commodities and which may include towns, farms, seignories, and other settlement forms. Hence, the sixteenth-century English settlement of lands escheated in Southwestern Ireland from the rebellious Earl of Desmond and his confederates was known as the Munster Plantation, the goal of which was to "plant" loyal English subjects into a hostile Irish landscape (Delle 1999), while the early seventeenth-century Ulster Plantation brought "British" subjects, both Scottish and English, to the northern counties of Ireland (see Lyttleton and Rynne 2009). The same concept of plantation informed the early English settlement of the New World, including the Plantation of Virginia and Plymouth Plantation; to this day the US state of Rhode Island is officially named the State of Rhode Island and Providence Plantations.

The concept of plantation as colony was similarly transferred to the initial British occupation of the Caribbean island of Barbados, which began in 1627. During the early seventeenth century, the British settlement of Barbados roughly followed the models established in Ireland, Virginia, and New England, inasmuch as the settlement of the island was marked by the establishment of relatively small farms, worked primarily by British yeomen and indentured servants, assisted by a relatively limited number of enslaved Africans. In the 1640s, large-scale sugar production was introduced to Barbados. Based on antecedents in Dutch-controlled Brazil and the Atlantic islands (Madeira, the Azores, and Cape Verde islands), the introduction of sugar cane production to Barbados resulted in the development of the plantation system, worked primarily with enslaved African laborers and their descendants. By the end of the eighteenth century, the term "plantation" would lose its sixteenth-century connotation and would primarily be used to describe a large, privately held estate, worked by coerced labor, and that produced agricultural commodities for export back to Europe.

While some work has been done on the earliest "plantation" sites in Ireland (Lyttleton and Rynne 2009), Virginia (e.g., Noël Hume 1982), and New England (e.g., Deetz 1996), the majority of work defined as plantation archaeology has focused on the later manifestation of the plantation system and includes excavations and analyses of plantation great houses, overseers' houses, industrial works, and the quarters and villages of enslaved and other coerced workers.

Historical Background

Although plantations in the US South were the focus of archaeology as early as the 1930s (e.g., Ford 1937; Noël Hume 1963), much of this early work was focused on reconstructing architectural details of the grand houses of elite plantation owners and rarely if ever considered the plantation as a unit of analysis (see Singleton 1985). The genesis of what is currently referred to as plantation archaeology can be traced to two projects, one conducted in the US South in the late 1960s and early 1970s, the other on the island of Barbados in the early 1970s. In the former, Charles Fairbanks led a team in the excavation of slave housing at Kingsley Plantation in northeastern Florida (Fairbanks 1974), in the latter, Jerome Handler and Frederick Lange led an archaeological investigation of the Newtown Plantation on Barbados (Handler and Lange 1978). In both projects archaeologists sought to understand the nature of the lives of the workers enslaved on the plantations within the context of the global commodities markets of which they were a part. In the case of the Kingsley Plantation site, Fairbanks and his students excavated slave quarter

sites. On the Newtown Plantation site, Handler and Lange concentrated their efforts on analyzing the skeletal remains and material culture recovered during the excavation of a slave-period cemetery. In both cases, the archaeologists analyzed material culture to determine the degree that African cultural traits survived in the New World and in both cases appear to have been surprised that no discernible pattern of survival could be detected archaeologically.

In the later 1970s and into the 1980s, an increasing number of plantation sites were excavated, particularly in the US South. Due in large measure to heritage management laws being passed by both the United States government and by the governments of its constituent states, large development projects in the US South began to incorporate archaeological investigations into preconstruction impact reports filed with various government agencies. Several important archaeological studies resulted from what was generally referred to as cultural resource management (CRM) studies on former plantations. Even where excavations were not mandated, thoughtful landowners occasionally funded excavations before destroying plantation sites.

Among the first plantations to be systematically excavated and analyzed was the Cannon's Point Plantation, the focus of a dissertation project in the early 1970s. The project, led by Fairbanks's student John Solomon Otto, was conducted on one of the barrier islands off of the coast of Georgia; the site was threatened by a planned subdevelopment on the island (Otto 1984). Rather than try to identify continuities with African antecedents, Otto focused his study on examining the plantation as a manifestation of complex society. Understanding that the hierarchical nature of the plantation economy would likely be reflected in the material culture of those who lived and worked on the estate – because plantation society was structured by both race and class – Otto hypothesized that status differentiation should be visible between the planters and overseers, and the overseers and slaves. Although status differentiation could be inferred based on the economic class of the parties involved, Otto's greater contribution was in his methodology which considered the plantation as an integrated system that included a number of cultural and physical features.

Practically simultaneous to Otto's study in Georgia, William Kelso began a series of salvage excavations on the site of the former Kingsmill Plantations near Williamsburg, Virginia. Reportedly as part of a purchase agreement through which the Anheuser-Busch Corporation acquired the land from the Colonial Williamsburg Foundation, the corporate owners of the Kingsmill tract agreed to fund archaeological investigations ahead of brewery, theme park, and upscale gated community development. Over the course of several years in the early 1970s, Kelso excavated 15 sites on the sprawling Kingsmill property that ranged in date from the early seventeenth through the late eighteenth century. The Kingsmill project succeeded in documenting how plantation landscapes had changed during the crucial moment when colonial investors shifted their strategies from rent extraction from tenant farmers to tobacco plantation production using enslaved African labor. At Kingsmill, Kelso was able to document how architectural styles and technologies changed during the seventeenth and eighteenth centuries. Notably, Kelso's project was among the first to identify "root cellars" in slave quarter sites, a feature now commonly recognized in earthfast structures associated with African descent people in Virginia (Kelso 1984). As had been the case with Otto's study, Kelso had the great advantage of examining numerous components of the site and thus contributed to the developing methodology of plantation archaeology, particularly concerning diachronic changes in plantation landscapes. In a similar project, Wheaton and Garrow analyzed material culture from two plantation sites known as Yaughan and Curribbo in the low country of southeastern South Carolina. By comparing assemblages from three slave quarters from the two plantation sites, the archaeologists focused on interpreting how enslaved populations adapted to their conditions of plantation life and labor, using the processual concept of acculturation to frame their analysis.

Changes in plantation landscape and social organization in the United States did not end

with the abolition of slavery following the cessation of the US Civil War. In another landmark plantation study funded by virtue of heritage management legislation, Charles Orser documented the transformation of the plantation landscape of Millwood Plantation, once the property of the Calhouns, one of South Carolina's wealthiest and most powerful families. In his study of post-emancipation Millwood, Orser used archaeological evidence to analyze how both emancipated workers and their former slave masters adjusted to the conditions of the postbellum south and how the material realities of plantation life were transformed in such a way as to reinforce the existing plantation social hierarchy through the agency of tenant farming and sharecropping. Orser's remains one of the few studies of an America plantation to focus specifically on post-emancipation social structures; his study is also notable for being among the first plantation studies to break from the constraints of the methodologies and theoretical constructs of processual archaeology, using a Marxian framework to understand the material record of economic and social constructs (Orser 1988).

The practice of plantation archaeology has not been restricted to the United States. Inspired by the success of plantation archaeology in the US Southeast, several archaeologists subsequently conducted archaeological projects on Caribbean plantation sites. In the early 1980s, Douglas Armstrong undertook the archaeological investigation of Drax Hall, a late seventeenth−/early eighteenth-century Jamaica sugar plantation. Armstrong's study was notable for recognizing the importance of house yards to enslaved African-Jamaican plantation workers, as well as for his theoretical approach which sought to understand how plantation culture was transformative for all those enmeshed within it (Armstrong 1990). In a later study at Seville Plantation, Armstrong and his students were able to document variation in the spatial layout of temporally distinct slave villages within the same site (Armstrong and Kelly 2000). Barry Higman, an Australian historian who lived and worked in Jamaica for several decades, simultaneously excavated a plantation site at Montpelier Plantation.

In Montserrat, the social geographer Lydia Pulsipher collaborated with the archaeologist Mac Goodwin to study historic land use patterns at Galways Plantation. Pulsipher and Goodwin's work was notable as it incorporated the study of provision gardens into plantation archaeology. In much of the English Caribbean, particularly Jamaica, enslaved workers were required to provide food for themselves, which was generally grown both in kitchen gardens found in house yards and on small farms which they maintained in peripheral areas of plantations known as provision grounds. Pulsipher and Goodwin's work was among the first to archaeologically explore this element of the plantation landscape (see Pulsipher and Goodwin 1999).

By the 1990s many plantation archaeologists accepted that individual plantations were systems integrated into wider global socioeconomic systems. Following the political economic turn in anthropology that was then current, studies like that conducted by James Delle on coffee plantations in the Blue Mountains of Jamaica took a regional approach to the archaeological analysis of plantation landscapes. Delle (1998) argued that plantation landscapes were multi-scalar phenomena that could and should be analyzed at several scales, including the individual household, the village of which households were a component part, the plantation, and the region, defined either geographically or socially (Delle 1999, 2002, 2011). Similar studies were conducted on the Caribbean islands of St. Eustatius and Tobago (see section "Further Reading").

Key Issues

Over the years, a number of key issues have been raised in plantation archaeology. Among the earliest and most persistent is the search for African "survivals," sometimes called Africanisms, cultural traits that survived the middle passage over the Atlantic and that are represented in the material culture of enslaved populations. Early archaeologists were perplexed as to why African cultural traits were so rarely found on plantation sites; some early archaeologists concluded that the

process of culture change, initially framed as acculturation, was rapid indeed. By the mid-1990s many plantation archaeologists abandoned the search for African survivals, and those still interested in the concept of culture change began to reimagine plantation communities as creolized communities, the process of creolization being one of ethnogenesis emerging from multiple antecedents and resulting in multiple local variants.

Among the most fascinating of creolized material culture are a variety of low-fired earthenwares recovered from diverse plantation communities throughout the Caribbean and North America. Initially recognized as being produced by indigenous communities in the US Southeast, these ceramics were initially referred to as "Colono-Indian Ware" but were later recognized as having been produced, at least in part, by enslaved Africans and their descendants on southern plantations (Ferguson 1992). Similar ceramics have been identified and analyzed on multiple islands in the Caribbean including Jamaica (where they are called "yabba"), Guadeloupe, St. Eustatius, and Nevis. That some of the ceramics have been found in unusual contexts (like the bottom of rivers) and with unusual markings have led some archaeologists to conclude that these ceramics were sometimes used in syncretic rituals by enslaved Africans and their descendants (Ferguson 1992).

In both Caribbean and US plantation contexts, low-fired, locally produced earthenwares shift from being dominant in seventeenth- and early eighteenth-century assemblages to nearly disappearing by the opening decades of the nineteenth (Higman 1998). This recurring phenomenon has led archaeologists to explore the degree to which enslaved plantation communities exerted some level of economic sovereignty through the establishment of modes of exchange that existed beyond the control of the plantation owners and their white managers, using such exchange systems to purchase refined earthenwares imported from Europe (see section "Further Reading"). In the postcolonial context, phenomena such as this have resulted in some reconsideration of the nature of colonial enterprises and the inherent social relationships that existed on plantations as integrated components of those colonial realities.

One of the key issues facing plantation archaeology is the degree to which plantation landscapes are preserved, and how such preserved landscapes are used to create historical interpretations about the plantation past. Private and public entities in the United States have gone to great lengths to preserve, restore, and interpret houses and landscapes associated with past American presidents. By historical coincidence, seven of the first ten American presidents (Washington, Jefferson, Madison, Monroe, Jackson, Harrison, Tyler) either grew up on or owned slave-based plantations as adults. Each of these houses has been preserve and is open to the public; at some of the houses, notably Washington's Mt. Vernon, Jefferson's Monticello, Madison's Montpelier, and Jackson's Hermitage, archaeology of the quarters of the enslaved has been incorporated into the historical interpretation of the houses and the early decades of US history. Presenting the issue of slavery to the public at such venues remains a difficult and sometimes controversial task.

Like much historical archaeology practiced throughout the world, plantation archaeology has increasingly incorporated local descendant communities and other stakeholders into the excavation, analysis, and interpretation of plantation sites. Among the most notable of such public archaeology programs is the long-term project conducted at the Levi Jordan Plantation in Texas (McDavid 1997). Again, like many different archaeologies now being practiced, plantation archaeology has increasingly been addressing issues of concern to local populations, including the difficult topics of race and racism, gender and sexuality, and power and resistance which are so deeply imbedded in the history and archaeology of plantations (see section "Further Reading").

International Perspectives

Plantation archaeology is, by its nature, an international pursuit. While plantation archaeology may have begun in the US South, it has been

conducted on a number of Caribbean islands including Jamaica, Dominica, St. Croix, Cuba, the Bahamas, Guadeloupe, and Martinique. In recent years plantation archaeology has also been initiated in East Africa and Brazil and at Mexican *haciendas* in the Yucatán and Guerrero, among other localities (see section "Further Reading"). With several notable exceptions, particularly from Great Britain and France, the majority of plantation archaeology projects are still being conducted by historical archaeologists either born in the United States or now living there.

Future Directions

While the future is difficult to predict, there are several directions that plantation archaeology might take. Clearly, the public interpretation of enslavement on plantations will continue to be refined. The scope of plantation archaeology can likewise be expanded; again with some notable exceptions of projects conducted on coffee plantations in the Caribbean (Singleton 2001; Delle 2011; Reeves 2011) and clove plantations in East Africa, the majority of projects have been conducted on sugar, tobacco, and cotton plantations, primarily in the Atlantic Basin, and primarily worked by enslaved African laborers and their descendants. As plantation archaeology moves forward, more sites in the Indian Ocean, Central and Southern America, the Pacific Islands, and the former French Indochina will likely open new avenues for interpretation. Similarly, as the breadth of commodity production expands to, for example, bananas, pineapples, rubber, sisal, and citrus, our understanding of the material life of the plantation will undoubtedly become broader.

Plimoth Plantation: Public Archaeology

Kathryn Ness
Plimoth Plantation, Plymouth, MA, USA

Introduction

Plimoth Plantation, a living history museum located in Plymouth, Massachusetts, is one example of public and publicly experimental archaeology in a museum setting. This museum is dedicated to the story of the seventeenth-century *Mayflower* passengers, later called the Pilgrims, and their Wampanoag neighbors who have lived in the area for millennia. Its key exhibits include a reconstructed Seventeenth-Century English Village and Wampanoag Homesite, a reproduction of the *Mayflower*, a Craft Center displaying traditional Native and European crafts, and a reconstruction of Plymouth's first 1636 mill, the Plimoth Grist Mill. Since its inception in 1947, Plimoth Plantation has relied on a combination of archaeological and documentary evidence to inform its exhibits, programs, and new research, all of which offer the public a way to engage with the Pilgrim and Wampanoag stories as well as archaeological and documentary research techniques.

Definition

The phrase "public archaeology" has been and continues to be defined in multiple ways. For some, it might mean conducting archaeological research that includes and engages a public audience, while for others it could be allowing the community of stakeholders to have some degree of control in the project (Society for American Archaeology n.d.). It could also include those who strive to increase awareness of archaeological resources and heritage through advocacy, political lobbying, journalism, and educational work. Yet another definition includes those who reenact historic events or time periods and experiment with traditional activities (Catling and Bahn 2009, 241, 246–247).

Public archaeology at Plimoth Plantation fits several of these definitions. It is perhaps best known for its reconstructed seventeenth-century Native and English structures where staff members experiment with historical lifeways and traditional activities, including cooking, animal husbandry, art, domestic activities, and building. Because much of our knowledge about this period comes from archaeological data, the Museum also offers ways for guests to explore local archaeological excavation and lab work and learn about previous excavations in the area. These guests range from professional archaeologists on vacation to young children who are experiencing their first introduction to the field, a range which offers multiple avenues for engaging the public.

Historical Background

Public archaeology has long been part of Plimoth Plantation. The Museum's founder, Henry "Harry" Hornblower II (1917–1985), was an avid amateur archaeologist who began excavating and exploring sites near his family's summer home in Plymouth, Massachusetts, as a teenager. This passion led him to study anthropology and archaeology at Harvard University under Professor John Otis Brew and put him in contact with other well-known archaeologists of the time, including Ripley P. Bullen and J. C. "Pinky" Harrington. Despite his training and excellent potential, Hornblower did not become a professional archaeologist, instead serving in the Armed Forces during World War II and ultimately joining the family's investment firm (Gomes 1985; Beaudry et al. 2003).

His love of archaeology and history never left him, however, and he became a trustee of the Pilgrim Society of Plymouth after returning from military service. By 1946, he began looking for ways to reconstruct the village erected by the English men and women who arrived aboard the *Mayflower* in 1620 so that the information gleaned from archaeological and historical research could be more accessible to the general public. In 1947, his project began to take shape when Plimoth Plantation, Inc., was established and a prototype "first house" was erected in downtown Plymouth. The Museum grew in 1953, when it opened a reconstructed fort-meetinghouse near the "first house." In June of 1957, the *Mayflower II*, a full-scale reconstruction of the famous ship, arrived in Plymouth and still further expanded Plimoth Plantation's mission (Gomes 1985).

By 1959, the Museum moved from downtown Plymouth to the Hornblower family's former summer estate, where it built a full-scale reconstruction of the original seventeenth-century village. This exhibit relied heavily on information from archaeological excavations and local restoration projects. When completed, the houses in this newly constructed village were furnished with antiques and populated with mannequins, giving Museum guests a static idea of how the houses might have appeared in the 1620s.

Also in 1959, Hornblower hired Dr. James "Jim" Deetz, a young archaeologist from Harvard University, to assist in creating the Wampanoag Homesite exhibit, which was in itself a prime example of experimental archaeology in that it included stone tool-making demonstrations and a reconstructed bark house. Shortly after his arrival, Deetz excavated his first colonial site, the Robert Bartlett Site, at Hornblower's urging. This site fascinated Deetz who began to focus on the then-new field of historical archaeology and include his students in his work. Throughout the 1960s and 1970s, Deetz and his students, many of whom are still active historical archaeologists today, excavated dozens of colonial sites in Plymouth and neighboring towns, all of which helped refine today's understanding of seventeenth-century life in Plymouth Colony. The data from these sites became the basis for some of the foundational texts in historical archaeology, including Deetz's well-known work *In Small Things Forgotten: The Archaeology of Early American Life* (Deetz 1977).

The artifacts from these sites, in turn, became the basis of Plimoth Plantation's extensive archaeological collections. Today, the Museum holds over 50,000 archaeological artifacts from over a dozen sites in Plymouth and nearby towns. The artifacts range in date from ca. 8000-year-old stone tools to twentieth-century pottery and household trash, all of which offer information on centuries of daily life in the area. While only a small portion of the artifacts are currently on display at the Museum, exciting new initiatives are underway which will allow more of them to be accessible by both the public and researchers in a variety of digital, online formats.

While Deetz and his students were building the archaeology collections through their excavations, Plimoth Plantation introduced a different aspect of public archaeology when, in the late 1960s and early 1970s, it removed the antiques and mannequins from the Seventeenth-Century English Village and added reproduction furniture, animals, and live, costumed interpreters portraying the roles of actual residents of Plymouth Colony in the early 1620s.This transition to "living history" gave guests the chance to interact

with the objects and animals while also letting Museum staff experiment with historical lifeways, such as cooking, woodworking, harvesting, and animal husbandry (Fig. 1).

The Museum's exhibits expanded yet again in 1973 when it opened the Wampanoag Homesite (Fig. 2) where staff demonstrate traditional Wampanoag lifeways, including cooking, farming, boat building, house construction, and games. Unlike the Seventeenth-Century English Village, where some staff are "in character" as specific historical figures, staff in the Wampanoag Homesite interact with guests as modern Native people who are eager to share their culture and traditional lifeways and talk about Wampanoag history.

Thanks to this experimental approach in both exhibits and on the *Mayflower II*, staff and guests gain deeper insights into historical daily activities.

Plimoth Plantation: Public Archaeology, Fig. 1 Guests enjoying Plimoth Plantation's Seventeenth-Century English Village

Plimoth Plantation: Public Archaeology, Fig. 2 Plimoth Plantation's Wampanoag Homesite

By using reproductions of historical objects, we are now able to better understand details like how dishes were used and broken, the ways in which clothing impacted movement and work, and how traditionally constructed buildings and ships aged and settled. This information, in turn, has the potential to offer new insights and possible interpretations for archaeological artifacts.

The experimental and experiential nature of the exhibits expanded, while the Museum's field archaeology program slowed down in the late 1980s and staff began to focus more on existing collections. New research projects involved reexamining the collections and material from earlier excavations, including ones done by Hornblower in the early 1940s (Beaudry and George 1987; Beaudry et al. 2003). While this work is still ongoing, the findings from these projects prove that the collections continue to have research potential and merit revisiting as we continue to learn more about the area and the period.

In 2014, Plimoth Plantation began supporting active fieldwork again when it partnered with Drs. David Landon and Christa Beranek of the University of Massachusetts Boston's Andrew Fiske Memorial Center for Archaeological Research to support a field school, Project 400, in downtown Plymouth. This continuing project includes a public dig in the heart of downtown Plymouth that has yielded the first evidence of the original 1620s colonial settlement as well as a better understanding of historical environmental change in the area and new insights into Native-colonial interactions. In addition to the excavation, field school students and instructors participating in Project 400 wash, sort, and create a preliminary artifact catalog in the Museum's ArchLab, a public archaeological lab space set up in its Visitor Center gallery.

Today, archaeology remains a prominent and public focus for Plimoth Plantation. Its archaeological collections continue to be reevaluated and examined by new scholars in light of recent findings, and its living history exhibits are regularly updated to reflect new discoveries. When the field school is in session, guests can meet and interact with students and participants in the ArchLab, and Museum members can take walking tours of the site with the Museum's curator and archaeologist. During October, Massachusetts' Archaeology Month, Plimoth Plantation offers numerous events designed to highlight archaeology, field work, lab work, and the Museum's collections. In keeping with the various definitions of public archaeology and its original mission, the Museum continues to offer a mixture of experimenting with historical technology and lifeways in the living history exhibits and opportunities to learn about ongoing excavations and new research.

Key Themes

Informing Living History Exhibits

Since its beginning, the Museum has relied on archaeological research to inform its living history exhibits. The 1972 excavation of the Allerton Site in Kingston, Massachusetts, for example, resulted in the first archaeological evidence of earthfast construction in New England (Deetz and Deetz 2000, 229). Using this data, architectural historian Henry Glassie designed a building in 1973 for the Museum's Seventeenth-Century English Village exhibit. This structure, known as the Billington House, was the first earthfast building in the village and marked a turning point in the exhibits as the Museum continues to use earthfast construction as a technique when building certain new structures in this exhibit.

Similarly, archaeological data helps determine how the houses are furnished. While texts and surviving/extant period objects serve to flesh out the archaeological record by offering details about items that do not survive in the ground, archaeological data is key for identifying the more ubiquitous items that are infrequently documented or preserved, such as pottery. Plimoth Plantation potters working in the Museum's Craft Center often rely on extant pottery examples to determine vessel shapes, sizes, and decorations. In 2016, for instance, staff potters examined two storage jars in the Museum's collections to get measurements, glaze details, and other information regarding the manufacture of these common utilitarian vessels. These potters then produced several dozen reproduction

jars that continue to be displayed and used in the Village. Other similar projects have resulted in reproduction slipware dishes that depict historical motifs and are used in the village or sold in Plimoth Plantation's museum shops.

Archaeology is equally important in the Wampanoag Homesite, where it provides information regarding both the physical layout and interpretation of the exhibit. The current configuration of the site reflects archaeological evidence from local sites that indicates that the Wampanoag people typically lived near the ocean during the summer months and further inland during the winter. Because the exhibit is located near several archaeological sites, the staff take care to preserve existing sites and teach the public about archaeology. The recent construction of two new *wetus*, or Native houses, in 2016 and 2017, involved small-scale archaeological testing, which was done in front of the public as an opportunity to teach about archaeological methods. When the houses were being built, staff put a new penny from the year of construction at the bottom of each posthole to prevent confusing modern and historical postholes. This process offered many opportunities to explain to guests the importance of protecting archaeological sites as well as the benefits of experimental archaeology, such as replicating historical construction techniques.

Interpretation and activities in the Wampanoag Homesite are also guided by archaeological evidence. When identifying materials to use in traditional crafts such as beading, staff often look to seventeenth-century sites with evidence of trade to ensure that they use accurate materials. Similarly, activities such as planting crops in the cornfield include burying fish with the seeds to act as a fertilizer, a method found at precontact Wampanoag sites and discussed by Native historian Nanepashemet (Assonet Wampanoag, 1954–1995) and substantiated by Pilgrim texts (Heath 1963, 81–82).

Thanks to ongoing research and excavations like Project 400, Plimoth Plantation continues to reevaluate and change its exhibits to ensure they are authentic. While excavations at other seventeenth-century sites in Europe, Virginia, and elsewhere in New England provide information regarding what was available to seventeenth-century consumers, Project 400's discovery of the original 1620s village in downtown Plymouth has yielded invaluable information about what the first European colonists actually owned and brought with them. The evidence of German stoneware and Native pottery at this site has emphasized historical Plymouth's involvement in the broader global economy and led the Museum to look for ways to express this trade in its living history exhibits.

Educating and Including the Public

Hornblower's and Deetz's early excavations could also be considered examples of public archaeology. Work at the William Bradford II Site in Kingston, Massachusetts, resulted in a 25-min long film that explains the excavation process and findings to a nonspecialist audience. While modern viewers might not consider the film *Colonial Six* to be an accurate representation of archaeological method, it offers an interesting and easily accessible description of the excavation and how the data it generated was used by Plimoth Plantation.

In addition to developing films, at least one of Deetz's digs was featured in an article in the popular *Yankee Magazine* that included a solicitation for volunteers at other upcoming digs. This call for assistance was answered by over a dozen letters from individuals who were interested in participating, many of whom were teenagers who wished to get experience excavating prior to deciding on future courses of studies.

Plimoth Plantation continues to support budding archaeologists in multiple ways. Its education department regularly includes archaeology and archaeologists in its teacher training workshops and offers programs geared toward helping scout troops earn their archaeology badges. The Museum's internship program also regularly includes at least one position for an advanced undergraduate or graduate student to help with the Museum's archaeological collections. In some cases, these interns also help develop educational programs and small exhibits to explain their work, the collections, or the history of archaeology at Plimoth Plantation.

In addition to engaging future generations of archaeologists, the Museum works to increase public awareness of archaeology by educating guests and volunteers about archaeological resources and methods. Walking tours of downtown Plymouth and the Museum's campus regularly discuss local archaeological resources and the role they play in studying the past. Similarly, the public-oriented ArchLab in the Visitor Center is set up to teach guests about what happens to the artifacts (and archaeologists) after the excavation is completed. It offers a behind-the-scenes glimpse into how artifacts get washed, sorted, and cataloged in the lab while also giving summer guests an opportunity to engage with those participating in the Project 400 field school.

When the field school is not in session, this work is continued by volunteers who help to catalog and digitize Plimoth Plantation's archaeology collections. In most cases, these volunteers have no prior archaeological experience and are therefore given basic training about archaeological methods, artifact identification techniques, and collections management. Some of them work in public areas where they interact with museum guests and share this information. Others work behind the scenes to put the training to use in working with the Museum's archaeological artifacts to help develop online resources that make the collections more broadly available to a digital audience.

During the month of October, Massachusetts' Archaeology Month, Plimoth Plantation sponsors numerous public archaeology programs, including a weekly lecture series featuring local archaeologists who share their latest findings. In 2016 and 2017, Museum staff and interns performed small-scale archaeological testing in one area of the Wampanoag Homesite exhibit to prepare for the construction of a new *wetu*. By virtue of being conducted in front of the public, it offered numerous opportunities to teach archaeological methods to visitors. In 2017, the two fall archaeology collections interns designed and implemented a series of pop-up programs that allowed visitors to learn about organic versus inorganic remains, create their own "grave rubbings," and piece together a broken reproduction pottery vessel. Throughout these programs, the interns were keen to explain how archaeologists use the techniques, what skills were required, and how to protect and preserve archaeological heritage.

International Perspectives

The story Plimoth Plantation tells is, by nature, an international one. It includes people from England, individuals who spent significant time in Amsterdam and Leiden, Holland, and the Wampanoag people of New England. People from other indigenous Nations, including the Narragansett, Massachusetts, and Pequot as well as French, Dutch, and Portuguese sailors and fishermen also crossed this landscape in the seventeenth century. In addition, all of these people were part of widespread trade networks that included various parts of the Americas, Europe, and Asia. As a result of this global story, public archaeology at Plimoth Plantation necessarily includes an international scope. While current projects are continuing to expand our understanding of the period and global interactions, the Museum is actively engaging with this research and including it in the living history exhibits.

Similarly, Plimoth Plantation caters to a modern international audience as guests to the Museum include individuals and families from throughout Europe, the Americas, and Asia. To help support this diverse market, the Museum has begun incorporating more text panels for visitors who prefer to read English or are more visually oriented, as well as increasing its online presence. This digitally global outreach includes ongoing work to digitize the Museum's collections and therefore make it available to scholars and guests who are interested in the story of seventeenth-century New England and archaeology but might not be able to visit in person.

Future Directions

The digital initiative is one exciting example of the future of public archaeology at Plimoth Plantation. By creating digital "exhibits" for non-archaeologists to see the archaeological collections, learn about specific sites, and explore

archaeological method and data, the Museum aims to expand its reach beyond those who are physically able to come to Plymouth. In addition, the Museum intends to support future research by making more technical databases of the collections available online for scholars and those interested in exploring beyond the public-oriented exhibits. These two resources will include textual data, such as finding aids and object descriptions as well as digital images and three-dimensional scans of selected objects – all of which have the potential to open new doors for research both about Plymouth and ways of sharing archaeology with the public.

For those who can visit the Museum in person, Plimoth Plantation continues to offer archaeology-themed activities, walking tours, lectures, re-created environments, and opportunities to experiment with historical lifeways. Visitors can see reconstructions of both seventeenth-century English and Wampanoag life and learn how archaeological data has contributed to our ability to build these exhibits. They can interact with Project 400 participants in the Museum's ArchLab and learn about its archaeology collections in the Visitor Center gallery. It is an exciting time for public archaeology at Plimoth Plantation as the Museum leverages new discoveries and technology to further its founder's vision of using historical archaeology to study, explain, and present the seventeenth century to a modern audience.

Poland: Cultural Heritage Management

Arkadiusz Marciniak
Institute of Prehistory, University of Poznan, Poznan, Poland

Introduction

Polish archaeology belongs to the Central European school of archaeological thought (e.g., Härke 2002; Marciniak 2006). It is a specific version of the culture-historical school characterized by diffusion and migration as major causative factors of culture change, spatial and temporal dimensions of material culture presented in the form of archaeological cultures and research strategies applying principles of inductionism and empiricism and concentrated upon describing and cataloguing empirical material, typological methods, and relative chronology. It has deliberately avoided any substantial theoretical debate.

Historical Background

Archaeology practiced in communist-governed Poland (1945–1989) was a state-funded discipline divided into four sectors with clearly defined roles and duties. These comprised (1) the Polish

P

Academy of Sciences in charge of conducting research and setting up academic standards, (2) university departments responsible for education supplemented by research activities, (3) museums aimed at handling collections and presenting them to the public, and (4) a state heritage body known as the Centers for Monument Protection to protect and manage archaeological materials and conduct small-scale rescue excavations. Protection of archaeological sites and objects was regarded as a relatively unproblematic and straightforward enterprise but treated with little esteem by the archaeological community, the politicians, and the general public alike.

Polish archaeology as well as cultural and archaeological heritage management policies and practices changed dramatically over the last two decades following the collapse of the Iron Curtain and the Poland's ascension to the European Union. This period has been marked by the implementation of European regulations and development of a new doctrine of archaeological heritage. It is further characterized by greater destruction of this heritage due to unprecedented large-scale large investments, intensive agriculture, commercialization, and new dimensions of public engagement (see also Lozny 1998; Kobyliński 2001a: 17). These developments led to the replacement of the hierarchical system of practicing archaeology by the application of neoliberal solutions in the archaeological heritage sector (Marciniak 2011). Investors became major sponsors of archaeological works and the market became a driving force in the archaeological practice.

Key Issues

Cultural and Archaeological Heritage Management

The idea of cultural heritage management was introduced in the post-1989 period following a steady move of funding responsibilities from the state to private developers. The concept of "management" implies decision making regarding the aims and means of attaining certain goals, selection of priorities, and a holistic approach to the research process. Managerial decisions based on argued presentation and justification has led to important changes in capturing archaeological data and assessing their significance and value. It also brought about new concerns regarding professional standards and accountability.

One of major developments in this period was increasing awareness of rapid destruction of archaeological sites and objects. Archaeologists have slowly become aware of their own responsibility to protect them (Kobyliński 2001a: 19). This has resulted in departing from hitherto used term "archaeological record" and replacing it by "archaeological heritage." It has been defined by as a finite nonrenewable physical and material resource. Each element of this heritage arguably possesses a unique value and collectively contributes to the cultural richness of the country and increasing understanding and knowledge of past societies. Consequently, archaeological substance has shifted from the scientific to the public domain and has been ascribed its cultural and social significance (Kobyliński 2001b: 77). Archaeology as a discipline began to be perceived and practiced as a public service. Protection and management of archaeological heritage is then no longer a matter of concern of the academic community but the public at large.

Legal Framework of Protection and Management of Archaeological Heritage in Poland

The last decade of the twentieth century brought about the emergence of a number of significant charters and conventions dealing with the conservation and preservation of cultural heritage issued by ICOMOS and the Council of Europe. They offered responses to emerging conservation and heritage issues. The questions they raised had a profound impact upon establishing a new doctrine of archaeological heritage in Poland as well as across Europe more generally. Particularly important were the 1990 ICOMOS *Charter for the Protection* and Management of the Archaeological Heritage (Lausanne Charter) and the European Convention on the Protection of the Archaeological Heritage of 1992 (Malta Convention). They defined policies for the protection of the

archaeological heritage as constituting an integral component of policies relating to land use, development, and planning as well as of cultural, environmental, and educational policies at international, national, regional, and local levels. Less influential proved to be the 2000 Council of Europe's European Landscape Convention addressing protection, management, and enhancement of the European landscape.

Implementation of numerous issues advocated by these conventions has significantly broadened and strengthened the goals of archaeology to include, alongside research and valorization, also the integrated management, protection, and promotion of common shared archaeological heritage. Sites need be integrated within the historic landscape, viewed holistically and not any longer perceived as consisting of only monumental objects. This approach can be seen as an outline of the new Polish doctrine of archaeological heritage.

These issues were combined in new legislation known as the Protection of Monuments and the Guardianship of Monuments Act, which was passed by the Polish parliament in 2003. The provisions of the Act stipulate that all archaeological sites regardless their quality and significance are protected by law. Investors have been officially obliged to cover all costs of preventive archaeological works including excavations, documentation, analysis, and publication of the results. Their research standards should remain identical to that of research projects. It is required that excavated materials are professionally analyzed and preferably published. They need to undergo proper conservation, whenever needed. A legislative framework for large-scale rescue projects is provided by the Space Management and the Building and Construction Act as well as the Law for Highway Constructions in Poland, both passed in 1994.

Institutional Framework of Protection and Management of Archaeological Heritage in Poland

The new legislation led to considerable changes in the organizational structure of institutions responsible for protection and management of archaeological heritage, in particular in the context of the dynamically growing number of preventive archaeology projects. This structure, however, has been in a constant flux resulting from different solutions put forward by subsequent governments. Consequently, an effective administrative system in this domain is still lacking. At present, there are two major institutions responsible for protection and management of cultural and archaeological heritage operating within two different administrative contexts.

The National Heritage Board of Poland is the state agency responsible for the national heritage. The office reports directly to the Minister of Culture and National Heritage. It is officially responsible for implementing the State's policy in the domain of national heritage. Its major objectives comprise setting up standards in the protection of national heritage, recording, documenting, and maintaining this heritage, and presenting it to the public.

At the same time, protection and management of cultural and archaeological heritage is the sole responsibility of the offices of the Provincial Conservator of Monuments operating in each of the country's 16 country provinces. They are responsible to the Provincial Governor, who himself is responsible to the Prime Minister. These offices are in charge of preparing and implementing the system of protection of culture heritage in their regions, collecting and archiving information about this heritage, monitoring existing cultural resources and integrating cultural heritage with natural landscape, spatial planning, and urban development. They are also responsible for issuing excavation permits and supervising all archaeological works.

Two contradictory solutions were also proposed in regard to management of large-scale preventive excavation projects. The first model assumed a leading role for a special institution operating under the auspices of the Ministry of Culture and National Heritage. It was in charge of selecting the contractor for archaeological works and their subsequent control. The provincial conservator offices were only responsible for issuing formal permits and remained in fact excluded from the decision making regarding other

elements of the project. The second model allocated a leading role in these projects to the provincial conservation offices. In both models, some degree of professional control over standards and quality of preventive works was retained.

The current situation is considerably different. A special central governmental body responsible for large-scale preventive works no longer exists. The National Heritage Board of Poland in fact decided to withdraw from this duty leaving a vacuum with no independent quality control of works conducted during large-scale infrastructure projects by any external professional body. Selecting the contractor for archaeological work is now exclusively in hands of the investor. Controlling and reviewing responsibilities of such work are conducted by the investor-appointed committees made up of investor-employed administrative staff, including archaeologists. This obviously rules out objectivity and neutrality of quality control.

Preventive Archaeology in Large-Scale Infrastructure Projects

The last 20 years were marked by huge infrastructure projects that demanded large-scale preventive excavations in association with pan-European and national investments. In particular, these comprised the pipeline from Siberia to Western Europe and the network of highways and expressways.

Preventive excavations related to the construction of the gas pipe in the early 1990s was the first major undertaking in the post-1989 period. It was carried out under the legal provisions established during the communist period but the wealthy Polish-Russian investor – EuroPolGaz – expressed good will and agreed to finance all archaeological works. The inception of gas pipeline preventive excavation projects initiated serious discussions on legal, organizational, and methodological standards of fieldwork and their implementation in practice. More generally, they set a precedent for the formulation of a new doctrine for the conservation and protection of archaeological heritage in the country. After some modifications, it was later implemented during highways projects.

The Polish highway program was passed in June 1995 and has been aimed at construction of 2,300 km of highways along with numerous expressways. Archaeological preventive excavations have been conducted in a strip of 80–100 m wide and have been pursued continuously since 1997. This huge undertaking involves a complex program which aims to detect, investigate, and document archaeological sites threatened by adverse effects due to scheduled constructions.

Large-scale infrastructure projects associated with these investments, built mainly by public and private investors largely in the Build-Operate-Transfer system, demanded preventive excavations and contributed to the commercialization of archaeological activities. This shift is manifested in the emergence of a large number of private archaeological companies, a tendency reported also in other countries of the region.

Major Challenges in Protection and Management Archaeological Heritage in Poland

Large infrastructure projects demanding archaeological works of unprecedented scale has rapidly and significantly reshaped Polish archaeology and created many unforeseen consequences. The discipline has been confronted with a huge number of excavations to be conducted at a fast pace and at a scale never experienced before. As a result, the vast majority of archaeological fieldwork in present-day Poland is almost exclusively carried out within the framework of preventive archaeology before the planned infrastructural projects. This includes survey, evaluation, recording, non-invasive prospection, and excavations.

One of the consequences of these developments is commercialization of the archaeological profession. The demand for contract work led to the setting up of numerous private archaeological firms and the emergence of a new and previously unknown category of professional group on the market. This move can undoubtedly be regarded as almost "revolutionary," especially considering the previously dominant model of small, almost "family" excavations.

With the advent of free-market regulations, the contractor is now being chosen on a commercial

basis in a system of tendering in which the decisive factor is exclusively the proposed price. Offers proposed by private firms are commonly chosen due to their lower costs and possibility to complete allocated tasks in increasingly shorter time slots. Academic institutions are slowly being removed from this market.

The increasingly tight financial conditions and extremely short periods for preventive archaeology work make it clear that an implementation of the standard research routines is difficult to achieve. For example, in one of the 2009 tenders for archaeological works, the investor required excavations of 25 ha be completed in a period of 3 months. In September 2008, in order to speed up the construction of highways in Poland, the General Directorate for National Roads and Motorways – the major investor – passed a law requiring a decision of the placement of any highway or expressway be linked with the permission for its construction. This means that all stages of archaeological works (e.g., survey, evaluation, legal and administrative procedures, as well as excavations) are to inevitably coincide with construction works.

To comply with increasingly tight requirements and lower tenders offered by the contractor, archaeological firms reduce a number of professional analyses they do and lower the standards of scientific documentation in order to accelerate the archaeological works and maintain the same level of income. Consequently, the quality of some of these works is below acceptable standards. Another unacceptable practice involves a deliberate falsifying of archaeological documentation to report an incorrect number of features. This situation led also to a growing number of unpublished archaeological data obtained during these excavations (see also Kobyliński 2006: 229–230). Unfortunately, neither the National Heritage Board of Poland nor provincial conservation offices have the necessary tools and resources to stop unethical and illegal practices.

The last two decades also marked the use of archaeological evidence for the creation of collective memories of local communities but in a manner different from past uses when archaeology was used to justify nationalistic claims. The public has become increasingly recognized as a stakeholder in the decision-making process regarding heritage management and its role as a consumer of the products of archaeological activity is apparent. Advances in information technology have enforced greater openness of archaeological activities and resulted in the breakdown of the previously dominant elitist attitudes of the professional archaeological circles.

This tendency has been manifested in a rapidly growing number of popular open-air festivals and fairs. The largest of them takes place annually in Biskupin, the icon of Polish archaeology, and has become a model for similar events organized by local museums across Poland. The first festival in Biskupin was organized in 1995 and was attended by c. 50,000 visitors (Brzeziński 1998: 499), and the number of spectators in succeeding years increased. The festivals proved to be commercially successful, though their anticipated educational functions have largely remained unmet. In order to attract visitors there is a tendency to create a mélange of various episodes from the past. Thus, the ancient Egyptians interact with the Slavs reenacting their medieval appearance, who themselves stand next to the prehistoric flint knappers. Serious public outreach projects do not exist.

Future Directions

Developments in protection and management of cultural and archaeological heritage are very dynamic in Poland. These processes have been recently further shaped by the global crisis and its consequences. Its impact on archaeology in Poland to date has not been as significant as in other countries in Europe and worldwide. Its effects has been diminished by a large number of continuing highway and expressway projects in relation to the Euro 2012 soccer tournament as well as a relatively good situation in the housing construction sector and real estate market.

Rapid changes in the last two decades led to absolute domination of private firms on the market of preventive archaeology contracts. Academic archaeology has had to accept that a vast majority of field activities has already been

undertaken beyond its control. This milieu needs to work out an efficient strategy of accommodating the rapidly growing number of archaeological materials that need to be systematically studied, published, and properly stored.

In overall, the last two decades in protection and management of cultural and archaeological heritage in Poland have been characterized by emergence of new challenges solutions but also by a series of unresolved problems and issues. The legal and organizational framework remains imprecise and malfunctioned in places. There is no professional institution in charge of setting up, effectively controlling and enforcing standards of preventive works, and public procurement law and free-market regulations are unclear contributing to lowering standards and quality of archaeological works.

Introduction

The extreme isolation, hostile environment, and the lack of human native population were factors that contributed to the understanding of Antarctica as a distant, inaccessible space empty of people and things. However, since its discovery in the early nineteenth century, expeditions were sent from different continents aimed at geographical exploration as well as commercial exploitation of its maritime resources. Archaeological sites on the continent and its surrounding islands are relatively recent and widely scattered and often relate to a single purpose use at a single point in time. They represent the remains of the limited range of human activities developed in Antarctica such as exploration, sealing, whaling, and scientific research. The conservation of historic sites, such as building, shipwrecks, and artifacts of the polar expeditions were a matter of concern since the signature of the Antarctic Treaty in 1959. Archaeology began in the late 1970s with a focus on the conservation of huts left by the expeditions associated to the Heroic Era of Antarctic Exploration. Since the 1980s, the South Shetland Islands region has shown a diversification of topics of interest including the study of the nineteenth-century sealing and whaling expeditions. Those research projects framed in academic research designs, and not driven by the needs of practical conservation, have moved archaeology into theory-driven research questions and multidisciplinary approaches. Archaeological research has been part of the complex heritage making process in Antarctica.

Definition

Antarctica is a vast continent managed and protected by the Antarctic Treaty. The Antarctic Treaty, signed in 1959 and entered into force in 1961, regulates international relations with respect to land and ice shelves located south of 60° S. Measures, decisions, and resolutions, which are adopted at the Antarctic Treaty Consultative Meetings (ATCMs) by consensus of the signatory states, give effect to the principles of the Antarctic Treaty and provide regulations and guidelines for the management of the Antarctic Treaty area.

Antarctica is the earth's only continent without native population, and human presence in Antarctica has been limited to the last 200 years. Because of this, human activities there have been centered around "expeditions," generally understood as journeys undertaken by a group of people with a particular purpose. Since the discovery of Antarctica in the early nineteenth century, expeditions have been sent there with multiple purposes, such as geographical exploration, scientific research, or commercial exploitation. Currently, under the agreements of the Antarctic Treaty System, the continent is devoted to peace and science, and expeditions are mainly either part of research actions organized by national programs or part of tourism activities. Due to its extreme climate, isolation, and distance, all – past and present – human activities in Antarctica face logistical and technical challenges.

Archaeology of polar expeditions involves a planned process of research, conservation, and management, led by professional archaeologists. Predominantly, it is focused on terrestrial sites that are expensive to study, given their isolated location, difficult access, and climatic conditions. Archaeology as an academic and professional field is very closely connected to material culture studies, historical research, architectural and naval history, and heritage studies. Archaeological practices are also associated with heritage

practices used to ascribe meaning and significance to human history in the polar regions.

Historical Background

Antarctic History

At the beginning of nineteenth century, explorers' descriptions of the Southern Seas aroused interest in the potential exploitation of their marine resources. Sealing and preindustrial whaling expeditions were sent by companies based in Australia, Europe, North America, and South America that contributed to the discovery of the South Shetland Islands in 1819. Since that moment, exploration campaigns organized by different governments were sent with the main purpose of performing geographical surveys. Cap. Thaddeus von Bellingshausen, who commanded Russia's first government-sponsored Antarctic expedition, reported significant discoveries on the Antarctic Peninsula area in 1819–1821. Other national exploratory expeditions were simultaneously launched by France, Great Britain, and the United States in the late 1830s. The expeditions of Capt. Jules Dumont D'Urville, Capt. James Clark Ross, and Capt. Charles Wilkes, who spent between two and three austral seasons in their voyages, continued making scientific observations and contributing to the charting of the Antarctic coastline.

Exploration and exploitation were often hand in hand, as expeditions that combined geographical discoveries and commercial interests were not uncommon. During the 1820s, many expeditions visited Antarctica such as those led by Capt. Benjamin Pendleton, Capt. Nathaniel Palmer, and Capt. James Weddell who inaugurated the involvement of the Samuel Enderby & Sons whaling and sealing company, which continued throughout the 1830s. The German expedition under the command of Capt. Eduard Dallmann in the 1870s was a later example of combining sealing with exploration.

Although the nineteenth century is often recognized mainly as a period of early exploration and coastal recognition, groups of sealers also landed and built their camps and shelters on the shore during the summer season at that time. Their ships were present in Antarctica during most of the nineteenth century until the end of 1880, with an uncertain starting date for this activity.

The 1890s marked the beginning of the Heroic Era of Exploration, a period of extensive Antarctic exploration sponsored by scientific societies. After the resolution adopted in the Sixth International Geographical Congress (London, 1895), exploring expeditions from nine different countries were sent to the continent. These expeditions were based on international cooperation and included researchers and explorers from different countries in a party. They had to work with complex logistics involving leaving parties that wintered in the Antarctic mainland. At that time, Antarctica was explored by Lt. Adrien de Gerlache (1897–1899) from Belgium, the British Southern Cross Expedition led by Carsten E. Borchgrevink (1898–1900), the German South Polar Expedition by Prof. Erich von Drygalski (1901–1903), the Swedish South Polar Expedition under Dr. Otto Nordenskjöld (1901–1904), the Scottish National Antarctic Expedition led by Dr. William S. Bruce (1902–1904), and two French Antarctic Expeditions led by Dr. Jean Baptiste Charcot (1903–1905 and 1908–1910). Other expeditions included the Japanese Antarctic Expedition under Lt. Nobu Shirase (1911–1912), the second German Antarctic Expedition led by Dr. Wilhelm Filchner (1911–1912), and the Australasian Antarctic Expedition by Douglas Mawson (1911–1914) (Headland 1989).

The early twentieth century was characterized by long island journeys, and several expeditions set their eyes on the objective of reaching the South Pole. Captain Robert F. Scott led the National Antarctic Expedition (1901–1904) and Lt. Ernest H. Shackleton the British Antarctic Expedition (1907–1909). The goal was finally achieved by the Norwegian Antarctic Expedition (1910–1912) commanded by Roald Amundsen, and the British Antarctic Expedition (1910–1913) led by Capt. Robert Falcon Scott. Symbolically, the arrival at the South Pole, and the failed Imperial Trans-Antarctic Expedition (1914–1917) under the command of Ernest Shackleton, marked the end of the Heroic Era of Antarctic Exploration. The stories of this period

involved a number of people of many countries not only the crews of the national and scientific expeditions but also those of the rescue expeditions which were sent from countries such as Argentina and Chile when the parties encountered problems to come back from Antarctica.

The most widely spread versions of the history of Antarctica focus their attention on this Heroic Era. Nevertheless 1890s is also the starting point of the industrial whaling exploitation in Antarctica, when Norwegian and Scottish whaling firms, with the contribution and investment of capitalists from different countries, sent ships to investigate the possibilities of whaling around the Antarctic Peninsula. This marked the beginning of a new period of exploitation – industrial whaling – that had a great impact on the Antarctic environment, including the settlement of a permanent factory in the South Shetland Islands (Fig. 1). The data officially registered mention imposing figures regarding the facilities in Antarctica, including floating factories, shore factories, and factory ships and catchers, as well as the number of whales hunted from 1906 to 1930.

During the twentieth century, technological innovation permitted different ways of exploring Antarctica and reaching remote locations such as the first flight to the South Pole and back launched by the American naval officer Richard Byrd in 1929. After the Second World War, scientific research and exploration of the Antarctic continent increased, and other activities such as tourism and modern fishing and whaling began. The exploitation of marine resources continued unhindered until the restrictions and regulations established by several conventions of the Antarctic Treaty that started limiting these activities in the late 1970s and the early 1980s. As a result of the International Geophysical Year (1957–1958), a great number of research expeditions were organized, and more than 50 stations were established. Since then, the development of scientific programs has been growing, spreading, and diversifying as well as the human presence and the material infrastructure required for supporting them.

Antarctic Archaeology

Many of the expeditions sent to Antarctica during the nineteenth and twentieth centuries left material remains that could be studied from archaeological research perspectives. The conservation of historic sites, such as building, shipwrecks, and artifacts of the polar expeditions, were a matter of concern of the Antarctic Treaty. When the Treaty was signed, some particular sites and artifacts were considered to have significant heritage values and different countries committed to

Polar Expeditions (South) in Archaeology, Fig. 1 Remains of the Hektor whaling station at Whalers Bay, Deception Island, South Shetland Islands. (Photo Maria Ximena Senatore 2004)

preserve and manage them. As a result, in 1972, the list of Antarctic Historic Sites and Monuments (HSMs) was created, and any party of the Antarctic Treaty could propose a historic site to be listed. The number of sites included, as well as the legal framework and criteria set to designate and manage them, has been modified following the agreements achieved on the Antarctic Treaty.

In the context of the awareness of the need of preserving historical sites, archaeology began in the late 1970s with a focus on the conservation of huts associated with the Heroic Era of Exploration. Before that, archaeological techniques were used for helping in the process of identification and conservation of historic buildings, as well as in the recovery of artifacts for museum collections (Fig. 2). Pearson has characterized the beginning of archaeology in Antarctica as "The Hut Caretaker Era" in which the vast bulk of the archaeological work has been undertaken in relation to "the removal of ice from inside and around historic buildings, and the excavation, often through ice, of accumulated material inside huts, as well as of stores boxes and caches outside huts" (Pearson 2011: 29).

In the Ross Sea region, New Zealand began actions in the 1960s on the Scott's Discovery Hut, the Scott's Cape Evans Hut, and the Borchgrevink's Hut at Cape Adare with emphasis on restoration for exhibition (Harrowfield 1992). In 1977, artifacts were removed from ice Scott's Huts with the purpose of conservation In the 1980s the first major systematic professional archaeological excavation in the Ross Sea region was undertaken by Neville Ritchie and Nelson Cross at Cape Evans in 1987–1988 and 1988–1989. They introduced new technologies for archaeological excavations on ice. Since 2006 the conservation-related work continued throughout the present led by the New Zealand Antarctic Trust developing a comprehensive monitoring and maintenance program of work in place. Over 60 international heritage and conservation specialists have been engaged in the conservation of four historic bases, and more than 18,000 artifacts found there (i.e., Shackleton's 1908 base, Scott's last expedition base at Cape Evans, Scott's first expedition base at Hut Point, and Hillary's Hut at Scott Base).

In the Commonwealth Bay region, the removal of ice and reparation of the Douglas Mawson's Hut began in 1978 with no archaeologist in the party (Ledinghan 1979). In the mid-1980s, the Project Blizzard – a private party – carried out two expeditions to the site, in 1984–1985 and 1985–1986. In the first one, their work involved recording of structures by surveyors, architects, archaeologists, and a material conservator. Project

Polar Expeditions (South) in Archaeology, Fig. 2 Snow Hill Hut used by the Swedish South Polar Expedition under Dr. Otto Nordenskjöld (1901–1904). (Photo Maria Victoria Nuviala 2008)

Blizzard continued with the removal of ice from the hut and inaugurated for the first time in Antarctica the combination of archaeology and conservation in the same team – archaeologists Estelle Lazer and Angela McGowan and conservation specialist Janet Hughes – with methodological innovations that were appropriate to the extreme environment (McGowan 1987). In 1986–1987 the archaeologist Michel Pearson undertook recording work at the site for the Australian Heritage Commission leading the first conservation management plan for the Mawson's Hut site in 1991. The Mawson's Hut Foundation, in cooperation with the Australian Heritage Commission and the Australian Antarctic Division, funded several conservation expeditions to Cape Denison. In this context, noninvasive techniques were conducted such as terrestrial ground-penetrating radar and magnetometer surveys in 2009 and 2010 for the localization of specific artifacts (Henderson 2010). As a result of the research process, the management plan of the area has been regularly updated.

In the Antarctic Peninsula region, "The Hut Caretaker Era" began in the late 1970s with actions of reparation of the buildings and the retrieval of artifacts left by the Swedish South Polar Expedition under Otto Nordenskjöld. The actions began in 1979–1980 in the Snow Hill Hut (Comerci 1983) and later extended to Paulet Island stone shelter and Hope Bay stone shelter. The projects were developed by the Instituto Antártico Argentino with no archaeologist involved at all on it for more than 20 years. In the late 2000s, a conservator and the archaeologist Victoria Nuviala visited the Snow Hill Hut for the first time to organize an inventory and develop in situ preventive conservation of the artifacts collected previously and stored at the hut. The professional work finished and the reports of it were presented in the frame of the ATCM in 2010.

In the South Shetland Islands region, archaeological research has shown a diversification of topics of interest and ways of understanding archaeology. The research projects developed there were focused on the expeditions sent to Antarctica for commercial interest as sealing and whaling. In Livingston Island geologists Ron Lewis Smith and Hugh Simpsom recorded sites and collected artifacts belonging to sealing expeditions from 1950 to 1980 (Lewis Smith and Simpson 1987). It was the first notice of the identification of sealing huts settled along the South Shetland coastline, but archaeologists were not involved in this work. In the 1990s Hacquebord surveyed the whaling station at Whalers Bay in Deception Island that was in use in the first decades of the twentieth century and contributed to the elaboration of a management plan (Hacquebord 1992).

Archaeological research focused on nineteenth-century sealers-whalers' occupation in the South Shetland Islands framed in academic research designs not driven by the needs of practical conservation has been developed for the last three decades. The excavations of the Chilean archaeologist Ruben Stehberg began in the 1980s and were the first professional archaeological work in the Antarctic Peninsula sector (Stehberg 2003). In the 1990s the Spanish archaeologist Manuel Martin Bueno joint the Stehberg project in the South Shetland Islands to search unsuccessfully the remains of the Spanish Navio San Telmo that went missing in 1819 crossing the Cape Horn. Since then, no underwater archaeological investigation has yet taken place.

The work of the Argentinian archaeologists Maria Ximena Senatore and Andres Zarankin in the 1990s has moved archaeology into theory-driven research questions (e.g., Zarankin and Senatore 2005). Subsequently Stehberg joint the Australian archaeologist Michael Pearson and began a period of international cooperation with Senatore and Zarankin sharing information, databases, publications, and fieldworks organized by the Instituto Antártico Chileno (e.g., Pearson et al. 2008). During that period more than 30 of these sites have been found and marked along the coasts of the South Shetland Islands (Fig. 3). Some of these have been excavated and studied in more detail providing information about sealer's everyday experiences in land and the connections between sealing-whaling expeditions to capitalism expansion (e.g., Pearson and Stehberg 2006; Stehberg 2003; Zarankin and Senatore 2005). In the 2010s several fieldworks began to be organized by Programa Antártico Brasileiro and new lines of research in archaeology

Polar Expeditions (South) in Archaeology, Fig. 3 Excavated archaeological site belonging to nineteenth century sealers' hut in Peninsula Byers, Livingston Island, South Shetland Islands. (Photo Maria Ximena Senatore 1996)

and anthropology arose led by the Universidade Federal de Minas Gerais. Some of the sites recorded and surveyed in the 1990s and 2000s were excavated. Pioneering site recording laser scanning methods began to be used (Zarankin et al. 2011) and perspectives that combined interpretative archaeology and hermeneutic approaches to the sealing life on the camps were developed (Zarankin and Salerno 2016). The archaeological samples that have been collected along the three decades have been studied by associated researchers as part of zooarchaeological studies (e.g., Cartajena and Labarca 2007; Muñoz 2000), geoarchaeology (e.g., Villagran and Schafer 2011), and other artifacts studies (e.g., Moreno 2000; Stehberg et al. 2009).

Collectively, archaeological research in the South Shetland Islands has contributed to the understanding of the nineteenth century in Antarctica in a global, regional, and local scale (i.e., the effects of the process of capitalism expansion to remotes and unknown places, the role of sealing and whaling in the early exploration of Antarctica, and the everyday life in the sealing camps). For an overview of the academic production and data published on the sealing archaeology in the islands and the contribution that archaeological studies offered for the characterization of the sealing strategies during the nineteenth century, see Senatore (2018). In the 2000s, the conservation and management of nineteenth century archaeological sites have become a matter of concern for the scientific teams involved, as none of the sealing archaeological sites have been designated among the HSMs in the frame of the Antarctic Treaty (e.g., Pearson et al. 2010; Senatore and Zarankin 2011).

Key Issues/Current Debates

Key issues with archaeology of polar expeditions are linked to the role that archaeology and material culture studies are playing in the Antarctic heritage making process and the development of academic archaeology in Antarctica.

Heritage making process in Antarctica is a complex process that involves multiple levels (i.e., international, national, individual) and context (e.g., policy-making, tourism, scientific research). The Antarctic Treaty System, based on international agreements, offers the main context in which heritage-making occurs. Policies on heritage management and protective mechanisms available have been applied on the basis of the assessment of heritage values to sites and artifacts. In this context, archaeology has long been a valuable tool in the conservation of Antarctic heritage sites, especially in the sites associated to the Heroic Era of Exploration. However "the extent to which academically oriented archaeological research might further enhance the understanding

of the importance of the heritage sites has yet to be clearly demonstrated as so little academic work has been carried out to date" (Pearson 2011: 30).

The "rubbish or artefact dilemma" (Pearson 2004) was an example that expressed the concern of archaeologists about the negative impact that the measures taken under the Antarctic Treaty System could have in the material culture of Antarctica (Evans 2011; Roura 2008). In the late 1990s when Annex III of the Madrid Protocol entered into force, the Parties committed to removing wastes from Antarctica, and the remains of past activities not protected were subject to be removed. The "Guidelines for Handling of Pre-1958 Historic Remains whose existence or present location is not known" has provided interim protection of artifacts/sites predated 1958 until the Parties have had time to assess their significance and consider their inclusion into the protection system. In 2002 the Annex V on Area Protection and Management of The Madrid Protocol entered into force as the legal framework for the protection of Antarctic historic sites. Later, more specific criteria for the designation of sites were established by the "Guidelines for the designation and protection of Historic Sites and Monuments" in Resolution 3 (2009).

Even though the designation of HSM is aiming at the conservation of the common inheritance of all nations, this protective mechanism could be used as a way of asserting national interest on the continent. Antarctic heritage discourses and practices are part of a complex political negotiation process in which the uses of material culture in the present have political consequences. Archaeologist and other social scientists are developing perspectives to study the meaning that material culture has in the context of the Antarctic Treaty System and in relation to nationalist discourses (e.g., Avango 2016).

Archaeological studies in Antarctica have made interesting contributions questioning dominant narratives of Antarctic history. There is a conceptualization of History in terms of exploration versus exploitation, even though they were connected. The narratives associated with exploration definitely play the leading role whereas those related to the exploitation of sea resources are subdued or simply omitted. They are often organized as a sequence of facts related to well-known characters at precise dates, and linked to national identity implications. In contrast sealing and whaling expeditions of anonymous characters, no precise dates or no memorable events, are not being link to national identities. Antarctic HSMs could be understood as a material dimension of the dominant narratives of Antarctic history. These selected remains, with a great emphasis on the huts of the Heroic Era, are considered to have heritage values as they represent the most valuable period of the Antarctic History. Their conservation has been, in consequence, naturally assumed as a duty. In contrast to this, the widely dispersed material remains linked to past exploitation activities of whaling and sealing are only scarcely considered in the conservation agenda of the Antarctic Treaty. Despite historic sealers and whalers' sites and remains not being included in the scope of Antarctic Heritage in the frame of the Antarctic Treaty, they have been focus of archaeological academic research in the South Shetland Islands since 1980s (Fig. 4). Archaeologists are proposing that the heritage values of oldest archeological sites are associated to being an irreplaceable part of the research process. Their conservation is needed for current and future studies about the human past in Antarctica. From that perspective, archaeologists are offering different basis for the assessment of heritage values to sites and artifacts.

International Perspectives

Under the Antarctic Treaty System, the Antarctic continent is internationally legislated and managed. In this frame, international cooperation is essential in developing and maintaining standards in the research and management of sites. In accordance with the Treaty, archaeology undertaken in Antarctica is a scientific activity with all results being open-source data. Some agreements among scientific teams are being settled to build shared databases and to design future archives of documentation produced during the development of the research projects on the sites. Finally, since

Polar Expeditions (South) in Archaeology, Fig. 4 Map of localization of the archaeological nineteenth-century sealing-whaling sites under research in the South Shetland Islands

the legal framework of the Antarctic Treaty involving research and management of heritage sites is a dynamic process, archaeologists have joint multidisciplinary groups of experts in Polar Heritage to help inform policy-making in Antarctica on heritage-related considerations. The ICOMOS International Polar Heritage Committee (IPHC) has been elaborating guidelines for the management of the archaeological heritage in Antarctica. The IPHC also provides guidelines for ongoing planning for the protection of sites where climate change may have an impact. For current work, see the IPHC website (www.iphc.icomos.org).

Future Directions

The development of academic archaeology projects will result in new perspectives of theoretically informed and science-based archaeological research. This will also drive the increasing of multidisciplinary approaches and the application of scientific techniques to the analysis of archaeological materials. Archaeological research will also continue current trends toward the use of technologies that minimize the impact on the sites, (e.g., ground-penetrating radar, laser scanning, photogrammetry) and reduce the high economic cost and time required to the development of archaeological survey, recording, and excavation in Antarctica (e.g., aerial and satellite remote sensing in archaeology). All this will have a positive impact on the development of new topics of research, especially those of underwater archaeology and contemporary archaeology.

Polar Exploration Archaeology (North)

Thomas Georgonicas
Department of Archaeology, Flinders University, Adelaide, SA, Australia

Introduction

Archaeological work on polar exploration of the north is focused in the Arctic region and the Arctic Circle. The first exploration of the Arctic is debatable, with some sources indicating the earliest being around 320 BCE. It was not until the mid-nineteenth century that exploration in the region was at its height. The search for a Northwest Passage, which would open a trade route linking the Atlantic and the Pacific, was the goal for most of the explorers at the time. Men such as John Franklin and his crew aboard the HMS *Erebus* and HMS *Terror* in 1845 set sail to find the passage, only to never be seen again. The many men who ventured into this region also left behind material culture, remnants of the age of exploration that today can help in the understanding of how other men survived such a harsh environment and how some men succumbed to it. Archaeology in the region to date is helping in solving how Franklin and his men all perished during their expedition, being used in locating the HMS *Erebus* and HMS *Terror*, and helping to understand how

exploration expeditions operated at the time and how it can help in the preservation of the Arctic's heritage.

Definition

The archaeology of polar exploration in the north is focused more in the Arctic region or the Arctic Circle which today consists of the Arctic Ocean and parts of Russia, Norway, Iceland, Greenland, Finland, Sweden, and Alaska. Archaeology of exploration is focused on expeditions in locating the Northwest Passage and the North Pole. Exploration in the Arctic can be dated back to the classical period of Ancient Greece up until present times.

Key Issues/Current Debates/Future Directions/Examples

The Northwest Passage Expedition of 1845, led by Sir John Franklin with 129 men onboard the ships HMS *Erebus* and HMS *Terror*, was one of the worst disasters in exploration history with all men supposably perishing (Bertulli et al. 1997). Search and rescue parties found material, remains, and graves of the crew at King William Island and Beechey Island. Personal accounts with the Inuits in the area confirmed the last survivors died from starvation (Bertulli et al. 1997; Rondeau 2010).

Owen Beattie, a professor of anthropology at the University of Alberta, led a team to excavate sites on King William Island and Beechey Island with the aim to find artifacts and skeletal remains of the 129 men from Franklin's doomed expedition. The "Franklin Expedition Forensic Anthropology Project" ran for 10 years; investigations at King William Island led to the discovery of archaeological artifacts and human remains. The human remains showed signs of scurvy and further examination showed signs of cannibalism (Beattie and Geiger 1987).

It was on Beechey Island that Beattie and his team investigated the graves of John Torrington, John Hartnell, and William Braine, all were crew members of the Franklin expedition. Their bodies were remarkably preserved due the conditions of the region and being buried under permafrost for over a 100 years. Autopsies were carried out on Torrington and found that lead poisoning had led to possible mental and physical illness, weakening his body before dying of pneumonia (Beattie and Geiger 1987). The source of the lead poisoning was first linked to poorly made food cans (Farrer 1993), and most recently, a probable cause was linked to the use of a unique water system onboard both ships that was poorly made and resulted in lead poisoning of the crew (Battersby 2008).

To date the wreckage of these ships have never been found but are the first and only designated historic site(s) of Canada that have yet to actually be found (Parks Canada 2012). As of 2012, Parks Canada in association with the Underwater Archaeology Service is resuming their search for the HMS *Erebus* and HMS *Terror* using remote sensing techniques and site excavations (Parks Canada 2012). Inuit knowledge of the wreck is crucial to the investigations; rescue parties in the search for Franklin and his men communicated with local Inuit people who claimed to have seen some of the men whom all later starved to death. Using oral history that has been passed down from generation to generation could hold the key to discovering the wrecks (Parks Canada 2012).

The lost Franklin expedition and its archaeological research background is one example of a current issue of polar exploration archaeology. Expeditions to the North Pole were also common at the time. The Ziegler polar expedition of 1903–1905 was a failed attempt to reach the North Pole. Unlike the fateful Franklin expedition, the expedition team led by Anthony Fiala were rescued with the loss of only one life (Capelotti 2011). In attempting to reach the pole, Fiala left supply caches at their base camp on Rudolf Island to their main base camp from a previous Ziegler expedition from 1901 to 1902. Very little is known about these sites, but their potential to provide new sources of archaeological data to study American polar ambitions at the turn of the twentieth century (Capelotti 2011). Research into the supply trail suggests that the supply route, which stretches 160 km, is a

potential archaeological piece of evidence of American polar exploration in the Arctic. The research also revealed the potential danger of the sites being damaged by unsuspecting tourists, altering the character of the sites and making any archaeological studies problematic (Capelotti 2011). Svalbard, a popular tourist destination in the Arctic region, with cultural and natural heritage sites, is an example of polar tourism's footprint in archaeological and heritage sites. It was up until the 1970s that the collection of artifacts was common in Svalbard. Looting has since become a offense and is policed but, unintentional damage such as trampled surfaces around historic sites with archaeological potential to rock cairns being made by visitors, although it can be argued that it erases some traces of past activities and replacing them with new traces and new narratives of the site (Roura 2011).

Unlike Antarctica, the Arctic region is not defined by a land mass and is mainly a body of water. Under international law, the North Pole and the Arctic waters cannot be claimed by any nation. With reports suggesting that the Northwest Passage is navigational than it has been since the 1970s, Canada has made its claim to the waters as part of their territory (European Space Agency 2011). What this means for the historical and archaeological sites in this region remains unclear and if any mining to the area could cause damage to the sites. The opening of the Northwest Passage as a possible shipping and trade route also allows places like King William Island and Beechey Island to be easily accessible to people for the first time but also means previously unreachable sites could now be explored by researchers.

In 2007 in a meeting of heritage organizations, it was declared that

> "the Arctic region is important for global processes and is to be considered as precious heritage for humankind. The region includes a number of unique and outstanding natural and cultural heritage places which require protection, improved management and international recognition due to their vulnerability" (Nordic World Heritage Foundation et al. 2007).

The archaeology of Arctic exploration and the heritage of sites relating to exploration efforts in the Arctic is becoming increasingly popular among researchers and towards tourists. The opening the Northwest Passage and the thawing of ice will make the area more navigational for both archaeologists and tourists. These sites will have to be continually monitored with information signs explaining their archaeological significance and their heritage value.

Polar Exploration Archaeology (South)

Thomas Georgonicas
Department of Archaeology, Flinders University, Adelaide, SA, Australia

Introduction

Archaeology in Antarctica has its routes in the work of whaling sites, some of the first examples of human occupation on the continent. In recent times, there has been a focus on the history of polar exploration in the region, most notably exploration during the heroic age from the end of the nineteenth century up until the early 1920s. This age saw a race to the South Pole, the exploration of resources and exploration in the name of science by men of the likes of Roald Amundsen, Robert Scott, Ernest Shackleton, and Douglas Mawson. Their pursuits in Antarctica left behind cultural material, archaeological, and heritage sites in the forms of graves, huts, monuments, and personal items that today are a link and physical reminder of our past in Antarctica.

Definition

The archaeology of polar exploration in Antarctica covers the heroic age of exploration from the end of the nineteenth century to the early 1920s, with further exploration expeditions continuing up until the 1950s. The sites themselves consist mainly of the material culture left behind by the expeditions that came to the continent, such as huts, monuments, graves, and material culture such as equipment and supplies. The sites are well known and well documented in Antarctica, with the main body of archaeological work involving conservation work and the protection of these sites.

Key Issues/Current Debates/Future Directions/Examples

The preservation of huts built and used by explorers and researchers is an issue in the archaeology and heritage in Antarctica. These huts were used as research bases for polar exploration teams from all over the world, mainly from the United Kingdom, Australia, New Zealand, the United States, and Norway. Archaeologically speaking, the surviving huts give Antarctica the attribute of being the only continent where the original human habitation may be seen today (Headland 2010). Of the 22 known sites, including the huts from the heroic age, only seven remain relatively intact, while four have become roofless ruins and ten have become nothing more than fragments (Headland 2010). The huts that remain intact contain many artifacts that relate to the heroic age of polar exploration. These artifacts range from food cans, personal items, lanterns, books, and research equipment. In Mawson's huts, for example, most of these items are literally frozen in time as heavy snow and ice has formed over some of the artifacts (McGowan 1987). The preservation of the huts has become a key issue in archaeology in Antarctica and Antarctic heritage. The huts were merely meant to last for as long as the expedition was to last. However, the huts that have survived did so due to numerous factors, including their location, climate, and the effects of human interference. Yearly, conservation groups assess the decay of the huts and help repair and conserve them from further damage. Conservation teams like the team of "Project Blizzard" visited the Mawson huts in the summers of 1984–1985 and 1985–1986 where

some of the first archaeological work in Antarctica begun as well as pioneering survey methods that were suitable to the environment (McGowan 1987).

The huts in recent times have had conservation work done by groups such as the "Mawson's Huts Foundation" (Mawson's Huts Foundation 2012). The huts built by Mawson during the Australian Antarctic Expedition from 1911 to 1914 numbered four in total, later three when two were merged into one hut. The huts included a magnetograph hut, used to measure variations in the south magnetic pole; an absolute magnetic hut, which was used as a reference point for studies in the magnetograph hut; and the transit hut for astronomical observations (Department of the Environment, Water, Heritage and the Arts 2012).

In January 2010, conservationists from the Antarctic Heritage Trust excavated a cache of Scotch whisky belonging to Sir Ernest Shackleton's failed expedition of 1907–909 (Antarctic Heritage Trust n.d.). These bottles, still containing the whiskey, were carefully thawed and examined in the UK by museum staff before three of the bottles were sent to the current owners of the Scotch whiskey for testing to help replicate the recipe that has since been lost (Antarctic Heritage Trust n.d.). Although the Scotch was later returned to the Antarctic to be reburied, there have been cases of artifacts being removed from site by private collectors. In January 1999, items taken from Robert Scott's Cape Evans Hut were returned 40 years after they were taken by a Royal New Zealand Air Force pilot when he was working in the region. The items were to be sold at Christie's auction house; when the New Zealand government raised the issue to the pilot, they were later given to the Antarctic Heritage Trust and returned to the hut by officials of the British government (Arthy 1999).

The unintentional destruction of sites and archaeological deposits is an important issue that needs to be addressed. "The Madrid Protocol" generated an urgency to clean up the Antarctic environment and, in doing so, increased the risk of the destruction of historic sites. Although the protocol in Annex III states that the cleanup should not damage historic sites or monuments, there was a lack of definition as to what constituted as a site, especially in regard to archaeological deposits scattered around historic sites and monuments (Evans 2007). The debate for "rubbish or relic" still continues; guidelines have been set up. Cleanups in Antarctica sites that date up to and/or before 1958 are protected by law. All artifacts located in these sites are to be disturbed as little as possible until properly recorded and evaluated (Evans 2007).

Antarctica's heritage sites and monuments are protected by numerous acts, one such act is the Antarctic treaty of 1994. The Antarctic treaty of 1994 protects the continent from mining minerals; it also lists all historic sites and monuments as protected, any disruption, looting, or intentional damage under Part II section nine of the treaty.

The archaeology of polar exploration in Antarctica will continue in the conservation and the investigations of the explorers' huts. Their conservation is important as they stand as a physical link to our past on the continent. Issues such as what counts as heritage in the region and the definition of archaeological deposits in Antarctica (i.e., relic or rubbish argument) will have to be settled before further damage to sites deteriorates their potential for archaeological research. The material remains in Antarctica narrate the history of past events in the region. When tourists set foot on these sites, they are helping in maintaining the memory of what happened there. However, tourist behavior may erase some of these traces and replace them with new traces. It must be made aware that the sites in Antarctica are not "frozen in time" but are used for a range of purposes and are transformed as a result (Roura 2011).

Polis

Benjamin M. Sullivan
Department of History, Cornell University, Ithaca, NY, USA

Introduction

The polis (or "city-state") was a characteristic polity of archaic (c. 700–c. 490) and classical (c. 490–323 BCE) Greece. The ancient Greek philosopher Aristotle said in the Politics (1253ᵃ2-4 = 1.1.9) "man is by nature a creature of the polis, and a man. . . without a polis is either subhuman or divine." Through a powerful if discontinuous tradition, the Greek polis set up the artistic and intellectual limits within which western civilization has framed its project.

Definition

Debate surrounds the appropriateness of translating polis (pl. poleis) as "city-state," but as long as the possibility of confusion with other city-state cultures is recognized, the term is adequate. In the classical period, "polis" had four basic connotations. First, a fortified settlement on a height, a sense that may extend back to the terminology of the Greek-speaking Late Bronze Age predecessors of the historical Greeks, still current into the classical period. Related to this locative sense was a second meaning, a nucleated settlement that controlled its agricultural hinterland. The third sense indicates this surrounding territory, though other words (*chora, gē*) differentiated this from the town itself. Finally, polis meant a political community.

Diachronically, its form contrasts both with the Mycenaean palace economies alluded to above and with the cities of the Hellenistic (323–30 BCE) period. Synchronically, it can be contrasted with the *ethnos* (pl. *ethnē*), the other primary category of Greek political organization,

which took root mostly in the NW and W of Greek-speaking lands. In *ethnos* regions, urban settlements did not emerge at all or emerged later in the historical period; when they did, they were often bound politically to larger regional associations. It is now understood that *ethnē* developed not before the poleis in a remote prehistoric past, but during the archaic period, subject to forces that caused the polis to rise (Hall 2002, 2007).

The lie of the land in Greece, small plains between often difficult mountains and hills, and inlets and islands, provided the geophysical mold that produced a patchwork of relatively isolated conurbations and likewise a great variety of social, political, and economic regimes. Yet, patterns can be discerned that cut through this diversity, and it is possible to establish at least three key attributes of the polis. First, political autonomy (*autonomia*) was at least a desideratum, even if a community's need for external military or economic assistance could make it impossible in practice. Second, poleis were generally small compared with other ancient polities (empires and federal states) and modern nation states. Some poleis had large territories (Athens, Sparta), but the average has been reckoned at 25–100 km^2, and while demography is murky throughout our period, only about 10% had populations greater than 10,000 in the classical period. Third, a sense of civic identity was characteristic. This was bound up with an (often imagined) sense of shared ancestry and with locality, as linguistic habits demonstrate. Polis dwellers referred to themselves as *Athenaioi* or *Korinthioi*, deriving their identity from an urban center (*Athenai*, *Korinthos*) in contrast with *ethnē*, the populations of which took their names (*Boiotoi*, *Thessaloi*) from the regions in which they lived (*Boiotia* and *Thessalia*). Thus, while some poleis could imagine being without land, territory was virtually a rule for polis status.

Historical Background

The Mycenaean and Hellenistic periods are not entirely arbitrary chronological limits. That poleis as such existed in the "Dark Ages," the period following the collapse of the Mycenaean world and constituting the Early Iron Age (c. 1150–700 BCE) in Greece, is doubtful, but the roots of the polis system should be traced into this period. The poleis did not disappear when the Macedonians assumed control at the end of the fourth century BCE and Greek cities flourished well into the Roman period. Nevertheless, since autonomy was a characteristic condition for the polis, ending an account with the classical period is justifiable.

The sophisticated apparatus of the Mycenaean palace-based economies collapsed in the decades following 1200 BCE. A period of unsettled life, depopulation, and radical loss of technologies, notably the Mycenaean administrative script (never widespread), followed. While recent archaeological work has relit this period, it seems to confirm a picture of isolation, stagnation, and poverty, though there are signs of recovery by the end of the tenth century. Continuities between Mycenaean Greece and the archaic period other than basic religious and agricultural forms are obscure, but it is notable that Mycenaean centers were roughly coterminous with regions where the polis emerged (Snodgrass 1980). It was also an age of poorly understood migrations, within the mainland and from the mainland to areas in the eastern littoral of Anatolia, where the major linguistic groupings (Aiolic, Doric, and Ionic) mirror mainland patterns. Whether the ethnic identities attaching to these linguistic groups, clearly marked by the classical period, were originally present is more doubtful (Hall 2002, 2007).

Archaic Period (c. 700–c. 490) The eighth century BCE saw further recovery, not least in the adoption of Phoenician symbols to create regional Greek alphabets (from mid-eighth century), material growth, and apparently a significant increase in population. Attica was seen as representative (Snodgrass 1977), but it is now questionable if the increase was as great as once believed, and likewise a question throughout Greece whether the signs of recovery indicate the presence of poleis.

Poleis in the political sense may have developed slowly. Burials may not correlate directly to population, and urbanism is not pronounced until

the following century. One way of tracking urbanization is through *synoikismos* (lit. "living together"), attested by classical writers about their ancient past. A notable example is Thucydides' notice (2.15.1-2) about the mythic Theseus' consolidation of Attica. His account of an original complex of small rural communities brought together politically without settlement change is unlikely in the long term: archaeology indicates a more complex process.

Another important phenomenon was colonization. The sending out of subsidiary settlements from "mother cities" was accomplished in waves beginning in the late eighth century, first westward to S Italy and Sicily, then in the seventh century toward the Black Sea and N Africa, with streams W again as far as Spain. This movement should be distinguished from modern colonization, inasmuch as it was not conducted by an empire to control a large territory with a lasting military presence. Ventures were instead small, and while ties remained with the metropolis, the *apoikia* was largely on its own. Hunger for new land should no longer be seen as the dominant cause; rather, trade, adventure, and personal enrichment should all be considered. Nor were the early colonies strictly a polis affair: Achaia, in the archaic period low on poleis, was a major colonizer (Hall 2007), and emphasis on individual founders points to private enterprise and loose organization, a picture confirmed by ceramic and mortuary evidence. This increase in mobility is part of general outward push by the Greeks, manifested in renewed contacts with Egypt and the Near East during an "orientalizing" century (750–650), with profound effects in art and other aspects of material culture.

Warfare was part of this expansion. Greek mercenaries, acting independently of their home political communities, fought in the East from the beginning of the eighth century BCE and imported objects and ideas from overseas. At home, apart from certain regions where terrain invited it, poleis were deficient in cavalry. The important soldier was the *hoplitēs* or hoplite, a heavy-armed infantryman who fought in open ground in a close-order formation known as the phalanx. The hoplite was clad in bronze helmet and plated body armor and carried a thrusting spear as his primary weapon; the most important defensive item was the shield, which dictated phalanx tactics. Physical evidence for the earliest hoplites comes as burials with arms and then from c. 700 as arms dedications at sanctuaries. The political importance of the hoplite is harder to judge. Aristotle believed that the hoplites became politically important with the support of the tyrannoi (see below), and early archaeological analyses used Aristotle's assessment to postulate a "hoplite revolution" in the early seventh century. This is now doubtful, but the evidence still leaves questions. As for public control, poleis may not have organized armies on a widespread basis until c. 600.

Fortification walls should be a secure index for the presence of a polis and theoretically provide a register for settlement size. Yet only 11 poleis were walled by c. 600, and since walls are notoriously hard to date, even this figure demands caution, though the prevalence of mud-brick construction and destruction by later occupation could obscure early walls. Recognizably civic architecture did not appear until the beginning of the sixth century. Nor can rule of law necessarily be inferred for the early archaic period. Recent research has shown that laws inscribed on stone (as opposed to later literary accounts) were mostly procedural and not the sweeping codes we might expect for a movement away from the vendetta toward a centralized legal system (Hölkeskamp 1992).

Monumental building was usually religious building, and such building, particularly the Greek temple, is intimately bound with the polis. The Dark Age saw religious activity centered on settlements, but the temple as such is difficult to discern. There are early expressions of the Doric order as early as the mid-seventh century, but fully stone temples do not appear till early in the next century. Some seventh-century projects were large (the Temple of Hera at Argos the largest at 15.1 × 46.6 m) and must have required considerable cost and a strong authority, but it is not clear that this authority was yet the polis. Tyrannoi (see below) were associated with building projects from the mid-seventh century, but it is not until the sixth century that monumentality becomes an

obsession – efforts such as the Temple of Artemis at Ephesos were already testing the limits of Greek building techniques by midcentury, and Sicilian buildings are sometimes staggering. The poleis had begun to make their land- and cityscapes grand with projects that suggest unprecedented central control and overall wealth.

Religion also encouraged interaction between poleis. One avenue was the international festival. Tradition held that games began at Olympia in 776 BCE, but whatever the accuracy of this date, it was not until the sixth century that the Olympic model could be reproduced elsewhere. Three major "panhellenic" games were inaugurated in the second and third decades of the sixth century, at Nemea, Delphi, and Isthmia. The circuit of games was fixed in a 4-year sequence, and the fact that the festivals were staggered so that they could be held in concert with the Olympics implies sophisticated interstate planning. Another avenue was the oracular sanctuary. Although Delphi acquired games in the early sixth century, here the oracle attracted attention, muttering prophecy not to predict the future but to provide mantic sanction for major decisions, both for poleis and individuals. After modest eighth-century beginnings, the Pythia (oracle of Apollo) soon gained great repute, as the attentions of Midas of Phrygia and Gyges of Lydia illustrate.

Political authority is key to tracking the genesis and development of the polis: "politics" means at its root the things of the polis. But when did the robust, variegated political lives of the poleis begin? Anthropological analysis has provided important cues and identified in the "kings" in Homeric epic an example of the "big man," a leader whose authority is achieved rather than ascribed. If we accept an evolutionary model, the next step should be the chieftain, the exemplar of ascribed authority in the nascent state. The Greek picture is complicated by the fact that later classical theorizing postulated a period of royal rulership in the period before the advent of aristocracy, but this was mostly invented tradition (Drews 1983). The phenomenon of tyrannoi (not to be confused with modern "tyrants") shows that rule by warlords was still a part of early archaic political life. The first of these dynastic rulers were the Kypselids of Corinth, beginning in the middle of the seventh century. Recent work has shown that tyrannoi were not necessarily "unconstitutional" rulers, rather one of many elite groups vying for political control (Anderson 2005). A controversial inscription from Dreros in Crete involving magistrates called kosmoi has been dated to the mid-seventh century. Yet early to mid-sixth century Argos is chronologically more typical. The relevant Argive inscriptions list officers (*damiorgoi*), and their language demarcates public and private spheres clearly, indicating central control and civic institutions.

A fundamental question is whether the archaic Greek economy was different in kind from modern economies or only in degree. Embedded in social and cultural milieux (von Reden 1997), the polis economy was unlike the autonomous modern market yet possessed familiar mechanisms such as coined money and even, in the classical period, rudimentary banking. Given its agrarian nature, questions about the character of farming are paramount. The idea that most agricultural producers were yeoman farmers representative of a "middling ideology" has been challenged (Hall 2007). It may be more appropriate to think instead of peasants of varying statuses focused on survival and powerful elite landowners. Nor should the importance of trade be neglected. The earliest Greek expeditions abroad (emporia), at Al Mina in the N Levant and Pithekoussai N of the bay of Naples, were similar to colonies but lacked settlements. Archaic Greek trade abroad culminated at Naukratis, a multiethnic Greek polis dedicated to trade established in the Nile Delta c. 600. Around the same time, the first coins appear at Ephesos. Probably originally a Lydian invention, coinage was at any rate perfected by the poleis, and by the end of the archaic period, nearly all the major poleis were producing coinage with distinctive obverse types.

Classical Period (c. 490–323) The full flowering of polis culture. It begins with the Persian Wars, military efforts that fostered a sense of shared identity among the poleis, at least as defined against a Persian enemy. The canons of architecture, politics, and thought fundamental to western culture find full expression in Periclean

Athens in the second quarter of the fifth century. Yet considered over the long run, this efflorescence was brief, with increased fragmentation in the later fifth century and fourth century giving way to the political overlordship of Macedon. Nonetheless, there is no discounting the period's achievements. The movement toward Hellenistic cosmopolitanism should not be seen as inevitable or a decline.

The necessities of agricultural production shaped settlement, but settlement was also intertwined with politics and culture. The general intensification of agricultural exploitation was uneven, with areas showing different patterns at different times. Methana (NE Peloponnesos) seems to have been settled more thickly in the fifth century after the buildup of an urban center, yet declined in the fourth century, and Boiotian Thespiai followed a similar pattern. On the other hand, the S Argolid retains its archaic settlement pattern until the fifth century, when many more rural sites appear (Mee 2011). Other than the larger poleis like Athens, most apparently concentrated their populations in urban centers – it is estimated that rural sites made up only 5% of the population of the S Argolid in the classical period. While colonization continued, its aims were now different, with larger poleis infringing on the territory or sovereignty of less powerful ones, a pattern visible into the Macedonian period.

War was endemic. The period begins with the surprising success of the Greeks against Persia and ends with the less surprising victory of Philip over a Greek coalition at Chaeronea in 338. In the interim was the Peloponnesian War (431–404), pitting an imperial Athens against a Spartan-led alliance. The traditional pattern, citizen phalanxes fighting small-scale battles in the plains, campaigns limited by agricultural demands, changed significantly. While short of modern total war, the new strategies expanded the arenas traditionally deemed acceptable for fighting. Warfare now clashed with the tempos of the agricultural year and involved more light-armed troops and mercenaries. Defense of both city and countryside became important, and fortification received greater attention, with more completely stone masonry, as opposed to walls of mud-brick socles with only upper courses in stone. Fourth-century walls used terrain contours to provide complete protection, with a concomitant extension of circuit length: the perimeter of the excellent fortifications at Messene ran 9 km. They could be equipped with sally ports, flanking towers, overlapping gates, and buttressed parapets. The formal ephebeia, citizen youths passing into soldiering adulthood, was first instituted at Athens in the second half of the century, its members given non-hoplite duties such as garrisoning border forts.

Political authority was now more centralized, expressed in monumental civic architecture and urban planning. An example of the latter was the template attributed to Hippodamos of Miletus. In Athens' port, the Piraeus, his ideas are manifested in a systematic accommodation for military installations, public services, and commercial facilities. A selective account of excavations in the Athenian Agora reveals an intense concern with civic building (full coverage: Camp 2001). After the democratic reforms of Kleisthenes (late sixth century) had transformed the political structure of Attica by emphasizing membership in artificial civic kinship groups over traditional regional loyalties, the Agora, transferred from an original location to the E, was made into Athens' civic center. A *bouleutērion* or council house accommodated the new democratic council, and boundary stones delineated public from private. On a ridge SW of the Agora, a facility (the Pnyx) to accommodate the citizen assembly was constructed with room for 8,000–12,000. After Persian destruction, the Agora was rebuilt and reorganized. Included now were *stoai*, multipurpose public porticoes. A round dining hall for the presidents of the council was built, doubling as a receptacle for Athenian weights and measures. During the Peloponnesian War, the Athenians added a new *bouleutērion* on the W side. The Pnyx was altered at the end of the fifth century: at least according to a later literary source, the aristocratic regime of the Thirty Tyrants reoriented the speaker's platform, which previously looked seaward, to face inland because they thought farmers were more sympathetic to oligarchy than members of Athens' powerful

fleet. A fourth-century (second quarter) refurbishing of the Pnyx was left incomplete. In the Agora, the temple of Ancestral Apollo took its present form around the same time, perhaps as a part of a larger civic renewal program centered on the figure of Lykourgos. A long base with statues of the Eponymous Heroes of the ten Kleisthenic tribes was set up on the W side, a fitting monument to the complexities and energy of the fourth-century Athenian democracy.

Greek religion was at its heart polis religion, a community of celebrants performing its two essential components, animal sacrifice and ritual. Monumental religious building ranged from borderland temples to the great urban complexes epitomized in the Athenian Acropolis building program (fifth century, second half). But it also included roadside shrines, peak and cave sanctuaries, and shrines attached to springs. Despite commonalities, the religious calendars for festivals celebrated by individual poleis expressed the variety of polis religion. These festivals provided a chance for the community to bond with commensality and competition. Originally a complex derived from annual agricultural changes, from a structuralist perspective (Osborne 1987), the changing nature of sanctuary dedications over the period indicates that worship became increasingly divorced from the springs of agricultural life – land outside the walls was seen as wild and opposed to the civic life of the urban center.

The environment and agricultural life was no less important to patterns of political authority. Agricultural involvement and individual modes of civic life influenced political arrangements (*politeiai*), with complex results (Osborne 1987). As Thucydides noted, the architectural grandeur of Athens belied military inferiority to Sparta, which remained an unwalled collection of villages into the fourth century. Sparta's citizens resided here, insulated from work. Brutal control of the serf-like helots' agricultural production allowed complete dedication to warcraft. Despite living in the town(s), they were nevertheless dependent on subjected labor in the countryside for sustenance. Even among poleis of similar regimes, town-country relations differed. Arkadian Orchomenos, an oligarchic ally of Sparta, had a fortified urban center with some amenities, but residence was largely extramural and included politically dependent surrounding communities, an arrangement suggesting a political sphere divorced from daily life. A variety of countryside-town relations also shaped democratic regimes. Elis had a loose political organization even after consolidation of its major territorial divisions in the early fifth century. Here were robustly independent outlying communities, and exceptionally, these villages could themselves support tiny outlier communities. Athens was early on populated from an urban center. The resultant system of villages (*dēmoi* or "demes") was after Kleisthenes' reforms made part of a complex system of political interdependence, with linking among demes, of demes to artificial tribes and of demes and tribes to citizen assembly. The city's civic, commercial, and religious facilities attracted resident aliens and its own hinterland population. Thus, Athens was like Elis in terms of the independence of its villages, but unlike in terms of the villages' relations to the political center, with the Attic demes much more tightly linked. Athens also stood apart with the buildup of its "empire" during the fifth century. As a result of the Persian Wars, Athens gained control the anti-Persian coalition. Allies weakened from tribute-paying and when they revolted were reduced by Athens' mighty navy. By midcentury, Athens had gained control of the alliance's treasury, parading its might in long tribute lists inscribed on huge stelai on the Acropolis and in the Panathenaic procession. Athenian hegemony deeply affected coastal and island poleis, often dependent on Athenian assistance but always subject to depredation by the Athenian fleet.

The independent smallholder became more prevalent by the fourth century. His private regime was limited in scope (polyculture was predominant) but could be complex in arrangement (Osborne 1987). A farmer might exploit various interests with differing intensity – flocks, arable land with slaves, a house and garden, and a rural tower where servants worked. Agriculture was preeminent, but trade also flourished, particularly as inter-polis bonds grew. Athenian mining operations at Laurion in S Attica exemplify

nonagricultural exploitation (Mee 2011). Production here had started in the Bronze Age, with lead ore exploited for its silver. Early efforts were aimed at exposed deposits, but eventually small tunnels ran to subsurface layers. The discovery of a vein early in the fifth century brought technological and commercial development to the fore. Vertical shafts were set in (some to more than 100 m) with adjoining galleries. Ore was processed in nearby workshops, and the washeries suggest considerable outlay. Working conditions were appalling, but the efforts allowed the Athenians to strike silver coins and fund the navy that built their hegemony. The state benefitted mostly, but powerful individuals were not without interests. The fourth century saw another boom in production, testified in Agora inscriptions set up by magistrates to record leases: while the state retained control, individual contractors made large profits.

Key Issues

Prehistoric Aegean archaeologists were traditionally more receptive to theories and methods from world archaeology, and increased exchange between the prehistoric and classical archaeologist is yielding fruitful results for the study of the polis. Increased emphasis on survey archaeology is one such development, which has been useful for tracking population shifts and land use strategies. Relations between Greece and the Near East, especially in the Early Iron Age and archaic periods, are a fertile field of study, but the classical period is also benefitting from new work on the Achaemenid Empire.

Current Debates

Arising from some 500 years of antiquarian, historical, philological, numismatic, epigraphic, papyrological, art historical, and archaeological work, debates about aspects of the polis are innumerable. Limiting them to some themes addressed above, the question how dark the "Dark Age" remains open. The question of a historical Homeric society is an unfinished chapter: to what extent do social, military, and economic literary episodes correspond with material culture? Snodgrass's pioneering synthetic methods on the eighth century (Snodgrass 1977, 1980) have been adopted for the archaic period. Early tyrannoi have been contextualized as a phenomenon not of unconstitutional monarchs but competitive elites (Anderson 2005), but the military side of the early tyrannoi needs more attention. Archaic coinage remains controversial, and the possibility that small denominations were more prevalent than previously thought has been a stimulus (Kim 2001). Near Eastern connections have been investigated for most aspects of the early poleis, and while there has been good work on mercenaries in the Near East (Luraghi 2006), resistance to the idea of eastern influence on the hoplite phalanx is perhaps conditioned by overreliance on the Homeric poems. De Polignac's landmark study (de Polignac 1995) on border sanctuaries argued that monumental sanctuaries were sited to mark out territory from other poleis, a thesis challenged on various grounds, but probably still valid for the late archaic period. Survey archaeology has proved a great tool for investigating the poleis' hinterlands and will continue to be invaluable, though particularly in demographic analyses, its limitations should be remembered. These are generally useful and meet the prerogatives of recent historical methods, but should be applied carefully, with the caveat that we will never be as sure about even late classical populations as we are of, e.g., the early modern period. Inscriptional evidence continues to be indispensable, with particular growth for the later poleis of Asia Minor. Dating of inscriptions by letter forms is also controversial, with recent opinion urging caution and favoring a downdating of fundamental inscriptions from imperial Athens. Ethnicity is an exciting field and has benefited from important recent studies, particularly Hall (2002) and Morgan (2003) (building on Roussel 1976). Economic history is well served in particular by the work of A. Bresson (2007–2008) and looks for ways to add to and advance past the fundamental contribution of M. Finley (1973) and the primitivist/modernist and substantivist/

formalist debates. Study of the role of women in the polis is hampered by dismal coverage in contemporary literary sources, but great strides have been made of late, with exemplary efforts at synthesis such as Connelly 2009 for women in polis religion.

International Perspectives

Since 1993 and culminating in the monumental Inventory of Archaic and Classical Poleis (Hansen and Nielsen 2004), the work of the Copenhagen Polis Centre has used both new and traditional approaches and a wide variety of categorizing rubrics to subject the Greek poleis (1,035 communities are included) to massive scrutiny. This is an invaluable resource, with contributions from a host of international scholars. Large international undertakings whether adaptations of venerable projects (e.g., SEG: epigraphy, Brill's New Pauly: all aspects of antiquity) or newer enterprises (e.g., PHI: epigraphy, The Ancient World Mapping Center: historical geography) and myriad recurring conferences and open-access journals supply grounds for international collaboration on polis research at a level unthinkable even a generation ago.

Future Directions

Continued cooperation between historians, classical archaeologists, and prehistoric Mediterranean archaeologists is welcome and will provide new syntheses. Willingness from prehistoric specialists to learn from ancient historians and those of more recent periods may advance study of the protohistoric polis. Classical archaeologists and historians will continue to benefit from cross-fertilization with anthropology and world archaeology and should be willing to let go of too rigid philologically based categorization if necessary. Likewise, excavators and surveyors could do well to learn from traditional ancient historical methods such as source criticism. Survey archaeology methodology and concentration on the Greek countryside will yield stimulating results, as will technological applications such as GIS, which holds great potential for studying all manner of polis developments.

Institute of Archaeology and Ethnology, Polish Academy of Sciences, Warsaw, Poland

Brief Definition of the Topic

In Poland, as elsewhere, excavations in the nineteenth century were conducted unsystematically and hastily, with the aim of acquiring interesting finds. Exceptional was Kalikst Jagmin's dig of 1873 at Łęgonice (central Poland) where a large barrow was sectioned along a W-E axis in order "...to uncover the very base of the mound and to expose a section which, showing the layout and quality of layers, would produce a visible proof of the manner in which this grave-mound was raised" (Jagmin 1876: 83). This isolated experiment produced one of the world's earliest examples of the relatively detailed observation and documentation of stratigraphy (Fig. 1). The first excavation manual published in Poland stressed that when digging multilayered mounds, "it is necessary to recognize... the height of every layer above ground level" (Majewski 1902: 195). Innovatory was Leon Kozłowski's method of excavating cemetery in Iwanowice by sequentially opening squares of 10 × 10 m (Kozłowski 1917: 2). Careful stratigraphic analysis is testified by multi-strata profiles of a cave site published by Stefan Krukowski (1921: 3–5 and Figs. 3 and 4).

In 1928 and 1930, Józef Kostrzewski explored a stronghold in Jedwabne with two small trenches. There he discerned nine layers which served to build the first relative chronology of medieval pottery (Kostrzewski 1931: 6, Fig. 2a, b). At Biskupin ca 3,000 m^2 were uncovered during the 1934 and 1935 seasons, and the five identified culture layers were defined using small tools only (Kostrzewski 1936: 11). Soil was sieved and overhead photography (from planes and balloons) was employed. Experimentally, finds from a limited surface were all recorded three dimensionally (Kostrzewski 1950: 5, 12). In 1936–1937, another 3,400 m^2 were excavated using 10 cm thick arbitrary layers (spits) which were recorded on plans at 1:10. on which all important finds were marked. A geologist analyzed 80 m of profiles (Kostrzewski 1938: 4. 9, 69, 132–9, Tables LXIX and LXX). This promising development was halted in 1939.

The handful of archaeologists who survived the War were confronted with the practical and theoretical problems posed by vast areas that the war destruction suddenly "opened" for

Polish Pioneers and Traditions, Fig. 1 A profile cut by Kalikst Jagmin in 1873 across a barrow in Łęgonice

P

archaeological investigation. The theoretical dilemma and the rapid development of unusually sophisticated responses are recorded in the dialogue between the two innovative archaeologists Tadeusz R. Żurowski and Włodzimierz Hołubowicz. In 1947, Hołubowicz stated the principle that "during excavation there are no less or more valuable layers, they are all equally important" (Hołubowicz 1947: 37). Digging and recording of a multilayer site must be based on a system of contiguous squares, so that "...it should be possible to reconstruct the system of layers with every item precisely localized..." (Hołubowicz 1947: 34). Żurowski had already written down many of his ideas in 1939, but they were not to appear in print until after the war. He maintained that a "culture layer is also a monument of the past (*zabytek*), even when it does not contain any finds of the material culture" (Żurowski 1949). He emphasized that "naturally formed layers may be interlaced with culture layers" (Żurowski 1947: 138) and thus urged the sampling of "every cultural and geological layer" (Żurowski 1947: 140) in order "to execute detailed geological, palaeobotanical, palaeontological, anthropological and other analyses" (Żurowski 1947: 137). He also believed that "topography is best reflected by contour-lines," the principle of his "topographico-stratigraphic" method of excavating and recording that was to ensure "reconstruction of the configuration of the surface in the moment of starting the excavation and of the every lower layer in sequence – period after period backwards" (Żurowski 1947: 137). "This means that we will always be able to show three-dimensionally or by contour-lines a given surface in its shape before so and so many thousand years" and "from the layout of contour-lines we can cut sections in any directions and we can draw profiles" (Żurowski 1947: 138). If we note also that all finds must be recorded "according to precise instrumental measurements" (Żurowski 1947: 137) and that "the interrelation of characteristic points at a drawing must be precise enough to make possible, even after several years, to impose the same measurement system and to achieve the same results in an unquestionable way" (Żurowski 1947: 137), we can see that there was a powerful guide to excavation method.

Hołubowicz in turn published an attack on the technique of "arbitrary levels" (spits) for exploring complex stratigraphic structures, which may be "...studied correctly only by defining cultural layers" (Hołubowicz 1948: 38, 40). Żurowski criticized Hołubowicz's zealotry but he made it clear that "exploration by arbitrary layers without discerning culture layers may lead to serious mistakes... because finds from very recent and very old culture layers may fall in the same arbitrary layer" (Żurowski 1949: 427). He illustrated this with clear drawings (Fig. 2) showing the fallacy of

Polish Pioneers and Traditions, Fig. 2 Graphic presentation of the fallacy of the exploration of complex stratigraphy by arbitrary levels (Żurowski 1949, Fig. 8)

what he called "the most primitive method" (Żurowski 1949: 462). He argued that "all finds must be localised in relation to a culture layer and not an arbitrary layer" (Żurowski 1949: 458). Such an attitude imposed treatment of every part of a site with equal piety, reinforced by the fact that the site "usually undergoes total destruction" (Zurowski 1949: 413).

Unfortunately, this promising "brain storm" died out quickly because almost all Polish archaeological "manpower" became engaged in the extensive "millennial" program which preceded celebrations of the millennial anniversary of the origins of Polish state in 1966. Numerous medieval towns and strongholds were excavated (c. 25 large sites a year), and the results were studied by multidisciplinary teams of archaeologists, architects, ethnographers and historians, which was called the "history of material culture." There was simply no time for discussions that did not offer immediate solutions to daily problems. Polish archaeologists became again very "practical," which meant that effectiveness counted higher than methodological rigor. Methods of excavation and recording that seemed too sophisticated were openly questioned (e.g., Dembińska 1954: 97). Very few archaeologists tried to follow the standards that had been set during the postwar decade, and Poland's important contribution to excavation methodology remains largely obscure despite attempts at its promotion (e.g., Urbańczyk 1999, 2004). The lack of theoretical discussion and of progressive methodology promotion resulted in stagnation. Digging in arbitrary levels found common acceptance (e.g., Mazurowski 1996: 4) and dominates until today.

Quick economic development after the political transformation of 1989 resulted in extensive investments in production and transport infrastructure, which made necessary to excavate huge areas. Again town centers and hectares of fields have been being excavated to free space for factories, habitation quarters, highways, and pipelines. Only some outsiders lucky to have a chance to dig slowly (usually abroad) have experimented, for example, with new methods of electronic recording (e.g., Urbańczyk 2002, 2011) (Fig. 3). Thus, 65 years later, we may recall Żurowski's bitter observation that "some prehistorians consider excavation technique too easy to learn it. Such attitudes, based on ignorance, inhibit progress. . ." (Żurowski 1947: 136).

Politis, Gustavo G.

Andrés G. Laguens
Museo de Antropología, Facultad de Filosofía y Humanidades, Universidad Nacional de Córdoba, Córdoba, Argentina

Basic Biographical Information

Gustavo Gabriel Politis (Fig. 1) is an Argentine archaeologist. He was born in 1955 at Buenos Aires, but he grew up in Necochea, a city 500-km south of Buenos Aires in the Argentine plains or Pampas. In 1978, he graduated as an anthropologist from the Facultad de Ciencias Naturales de la Universidad Nacional de La Plata, where he also made his postgraduate studies. He received a Ph.D. in 1984 on the basis of his dissertation about the archaeology of the "*interserrana*" area (the plains between the Tandilia and Ventania hill ranges) of Buenos Aires province. After his graduation, as a postdoctoral fellow (1984–1985), he stayed at the Department of Anthropology of the University of Kentucky, and was a Visiting Scientist at the Smithsonian Institution's National Museum of

Politis, Gustavo G., Fig. 1 Gustavo Politis

Natural History, and Visiting Scholar at the Center for the Study of Early Man at the University of Orono, Maine.

Before that, he held a fellowship of the National Research Council of Argentina (1979–1984) while he began his career in the teaching of archaeology. He was Assistant Professor (1980–1984) at the Facultad de Ciencias Naturales of the Universidad Nacional de La Plata, Argentina, where he taught American Archaeology and was Associate Professor (1987–1989) at the Universidad Nacional del Centro de la Provincia de Buenos Aires. Since 1993, he has held a tenured post at the same institution teaching American hunter-gatherers, while at the Universidad Nacional de La Plata, he continued as Professor teaching Method and Technics in Archaeology. He taught at different universities abroad as Visiting Professor as well, such as the Universidad Nacional de Colombia (1991, 1992), University of Cambridge (1991), University of Southampton (1992–1993), and Stanford University (2001).

In 1987, Gustavo Politis became researcher at the National Research Council of Argentina, where he developed his professional career, progressing up the hierarchies to his current position (2010) as Senior Research Fellow, the highest one. His main research activities were carried at the Museo de La Plata of the Universidad Nacional de La Plata and at the Núcleo de Investigación INCUAPA (*Investigaciones Arqueológicas y Paleontológicas del Cuaternario Pampeano*) of the Universidad del Centro de la Provincia de Buenos Aires (UNICEN), where he still develops his research and is Director. His work at the University also entailed active participation as academic councilor and later as Dean (1989–1992) of the Facultad de Ciencias Sociales (UNICEN), where he also promoted the foundation of the INCUAPA (1995). There he created the Doctorate in Archaeology (2005), where he currently is the Director. As professional archaeologist, he was President of the Sociedad Argentina de Antropología (2006–2009) and Editor of *Relaciones de la Sociedad Argentina de Antropología*, the most important academic journal in anthropology at Argentina.

Major Accomplishments

Through his research, Dr. Politis promoted a renewed emphasis on study of the archaeology of the Pampas, an area traditionally undervalued. From the beginning of his work in the area at the end of the 1970s, he demonstrated the importance of this region in the early peopling of the continent, and renewed discussions on human and megafauna coexistence (Politis 1984). Thanks to his encouragement, new projects and lines of research were opened in the region, and at the present time, many research teams are making important contributions, while recognizing its historical importance.

Particularly interested in hunter-gatherers, Politis spent long seasons between 1990 and 1996 at the Colombian Amazonas forest conducting ethnoarchaeological research among the Nukak, a recently contacted hunter-gatherer group. There he tested many assumptions about forest hunter-gatherers and developed models in relation to settlement and mobility, as well as advanced new insights in relation to subsistence

and material culture (Politis 1996). This experience was continued in his ethnoarchaeological research among the Hotï at Venezuelan Amazonia in 2002–2003, and among the Awá, at Brazil, which led him between 2005 and 2009 to make new ethnoarchaeological studies in an international project with Spanish and Brazilian colleagues.

Theory and the history of archaeology have been other major concerns and contributions by Dr. Politis. Within a perspective of the history of archaeology both in relation to theory and to politics, he made many important contributions that placed South American archaeology in the international arena. He was particularly interested in the sociopolitical contexts of knowledge production (e.g., Politis 1995, 2001; Politis and Curtoni 2011) and the positioning of South American archaeology in relation to global counterparts, colonialism, and world theoretical context (e.g., Politis and Alberti 1999; Politis 2003). His experience as an ethnoarchaeologist has informed theoretical considerations of this topic, especially in terms of its ethical implications (Politis 2001).

Gustavo Politis' research with Indigenous people is characterized by his commitment to the people with whom he works and a reflexive stand on the social role of archaeologists. He had an active and conspicuous participation in the first restitution of an Indigenous ancestor at Argentina ordered by law in 1994. This was particularly significant and symbolic as it was about a highly respected chief, Inakayal, who had resisted the advance of the State in nineteenth century over their territories at Patagonia and been kept at the National Museum as a specimen. This first repatriation had deep impact on native peoples, vindicating their struggles, as well as on scientists and ordinary people.

Dr. Politis has received numerous awards for his contributions to the profession including one of the most important recognitions in science at Argentina, the Premio Nacional de Ciencia "Bernardo Houssay" of Argentina, with which he honored twice both as junior (1987) and senior (2003) researcher. In 2003, he was distinguished by a John Simon Guggenheim Fellowship. He was invited as distinguished Lecturer, banquet speaker and to plenary lectures at international congresses in many opportunities. His book *Ethnoarchaelogy of an Amazonian People* (Politis 2007) was chosen by *Choice*, a premier source for reviews of academic books in the USA, as one of the outstanding academic titles of 2008.

Introduction

The archaeological site of the Roman town of Pompeii is located in Campania, Southern Italy, 8 km southeast of the apex of Mount Vesuvius. Pompeii as well as the nearby towns of Herculaneum, Stabiae and Oplontis were destroyed and buried when Mount Vesuvius erupted in 79 CE. In 1997, Pompeii, Herculaneum, and Torre Annunziata were declared World Heritage sites by UNESCO because they "provide a complete and vivid picture of society and daily life at a specific moment in the past that is without parallel anywhere in the world" (UNESCO 2019).

In ancient times Pompeii was situated on a low hill at the mouth of the Sarno River, about nine kilometers south of Mount Vesuvius. Both the river port and the shallow bay to the south were filled in by volcanic deposits during the 79 CE eruption which pushed the coastline outwards by more than 1 km. This was a total disaster for the inhabitants, but they have not been forgotten, because the 4-m-thick layer of volcanic debris preserved the city and most of its material goods.

The area was settled during the sixth century BCE by Greek traders coming from either Cumae, the first Greek colony in Italy, or from its subcolony Parthenope, later known as Neapolis ("New Town"), now Naples (Descœudres 1994, p. 5). Little is left of the Greek town, which lies beneath the Roman-period remains, but it was likely laid out along the principles developed by the Greek architect Hippodamos of Miletos (498–408 BCE) with an open plaza at the center, surrounded by a geometric grid of streets. Gates on each of the four sides gave access to nearby towns and ports. Remains of the Doric Temple built in the sixth century BCE still exist beside the later Roman Forum.

The town was enclosed by walls in the 470s BCE to protect the population from external threats, but walls did not deter the Samnites who in the 420s BCE swept down from the mountains and took over most of the coastal towns, except Naples. Pompeii was greatly enlarged, to its final size of 64 hectares, surrounded by a city wall pierced by seven gates. Solidly built Samnite houses, such as the core of the House of Sallust, survived over 400 years till the time of the volcanic eruption and the Samnite language, Oscan, was still occasionally used in graffiti. By then, however, the whole of Campania had been conquered by Rome and formal inscriptions were in Latin, as were most of the graffiti.

In 80 BCE, Pompeii became a Roman *colonia,* a town where veterans were resettled, which greatly increased the population. Public buildings were created or enlarged and included the Forum, a concert hall, baths, a theatre and amphitheater, and several temples. The city was divided into rectangular blocks or *insulae*, "islands," by a street system of north-south *cardines* and east-west *decumani*. The two main longitudinal streets, today called Via dell'Abbondanza (Street of Abundance) and Via di Nola, are crossed at right angles by the Via Stabiana. The *insulae* consist of a mix of large houses surrounded by smaller dwellings, shops, artisan workshops and a great many eateries.

Although Pompeii was not a city of any great political significance, it was wealthy and some of the private houses were enormous – the House of the Coloured Capitals, for instance, covers 2000 square meters, is beautifully decorated with frescoes and mosaics and encloses a courtyard and two gardens. The Villa of the Mysteries, a suburban villa just outside the walls, was partly a working farm, with a wine press and stables, but its dining hall has on its walls a magnificent continuous fresco, 17 m long and 3 m high, generally considered to be a masterpiece of Roman art.

The whole coastline was prone to earthquakes and two reliefs in the House of Lucius Caecilius

Jucundus show their effects: in one, the Temple of Jupiter in the Forum is toppled; in the other, the Vesuvius Gate collapses (Berry 2007, p. 237). In 62 CE, there was a catastrophic earthquake which almost totally destroyed neighboring Herculaneum while many buildings were damaged within Pompeii itself. Repairs were ongoing and costly: an inscription in the Temple of Isis records it was restored and enlarged at private expense after the earthquake (Berry 2007, p. 236). Restorations were still being undertaken at the time of the pyroclastic disaster that destroyed the town in 79 CE.

The main primary source for the volcanic eruption is the first-hand account by Pliny the Younger written as a recollection about 25 years after the event. In two letters to his friend the historian Tacitus, Pliny describes the progress of the eruption he witnessed as a 17-year-old while he was staying on the other side of the bay at his uncle's villa at Misenum. In the first letter, he describes the heroic deeds of his uncle Pliny the Elder, naturalist, writer, and commander of the Roman fleet who ordered warships to be launched with the aim of rescuing as many people as possible. Sadly, Pliny the Elder's rescue mission was cut short when he died in the arms of his slaves on the beach at Stabiae as a result of breathing the thick smoke from the eruption (Pliny the Younger, n.d.).

The current estimate for the population of Pompeii at the time of the volcanic eruption is of about 12,000 people (Lidz 2019), perhaps only half of the population at the time of the earthquake 17 years earlier. While archaeological evidence indicates that people remained in, or retuned to, the city after the earthquake, to repair their houses and public buildings such as the Forum and the Stabian Baths, some parts of the city may have been sparsely inhabited. For instance, only 22 bodies were found within the Insula of the Menander, a city block between Via dell'Abbondanza (Street of Abundance) and the Via Stabiana. This *insula* included four large houses and a dozen smaller establishments and should normally have housed a great many more people. Fifteen of the bodies were found in a group on the stairs of the largest house, the House of the Menander, and are presumed to have been fleeing together; they wore noticeably little jewelry and carried no money – unlike the adult and the teenager found in one of the bedrooms with bags of coins and silver objects (Allison 2006, p. 401, 405). One can speculate that the people on the stairs were servants, while those in the bedroom were members of the householder's families. It is the human drama of such discoveries that has made Pompeii so well-known worldwide.

Well before archaeology had been developed as a scientific discipline, the earliest known "digging" at Pompeii was done in the early 1700s for the purpose of extracting works of art for the villas and palaces of wealthy aristocrats. The lost city was not identified until 1763 when an architectural block bearing the inscription *res publica Pompeianonorum* (State of the Pompeians) was uncovered (Descœudres 1994, p. 42).

Shortly after, more systematic excavation began in 1765 when Spaniard Francesco la Vega became director of excavations. His method was to clear the rooms of each building to floor level and leave the excavated buildings in full view for the public to see. He also established the first overall plan of the excavations (Etienne 1992). The Temple of Isis was discovered in 1765 during his directorship. It contained human remains and objects from the ancient Egyptian religion which later fired the imagination of Edward Bulwer-Lytton (1803–1873), author of the highly successful novel *The Last Days of Pompeii*, published in 1834. During the era of the "Grand Tour," Pompeii became a popular destination as wealthy aristocrats, writers, artists, and architects from Britain and European countries developed a passion for travel to Greece and Italy to see the "birthplaces" of European art and culture.

One of the most important contributions was made by Giuseppe Fiorelli, director of excavations at Pompeii and Herculaneum 1863–1875. Fiorelli was an ardent Italian nationalist and creative thinker who introduced many new excavation techniques. With considerable foresight, he decided not to dig below the first-century levels, (which has probably preserved pre-Roman material) and established the system still in use of dividing the old city into nine "regions" (I–IX), which are then subdivided into their various

components. For instance, the House of the Coloured Capitals is VII,4,31 meaning house 31 in *insula* 4 of *Regio* VII.

Fiorelli's most spectacular innovation, however, was to fill with plaster the empty spaces left by bodies that had decayed in the solidified ashes. The results are the profoundly moving Pompeii casts which provide visitors with a vivid reminder of the human tragedy caused by the eruption. More recently, Fiorelli's plaster method has been replaced by techniques that use resin or liquid fiber glass to enable bones and other artifacts to become visible within the transparent cast.

Another archaeologist who made a significant contribution to the interpretation and display of Pompeii to the public was Amedeo Maiuri, director from 1924 to his retirement in 1961. Maiuri was the first to examine Pompeii's pre-79 CE history by excavating below floor levels in houses such as the House of the Surgeon. Maiuri aimed to showcase everyday life as it was in Pompeii at the time of the eruption by reconstructing streetscapes, walls, roofs, and interiors of houses and by restoring the vivid images of Pompeian life such of those in the wall paintings of the Villa of the Mysteries. The restoration of Pompeii has been influenced by the energies, visions, and strengths of the many archaeologists who have worked there. In addition, a growing awareness of advances in archaeological research among the current population of the modern city increases the chances of discovering more about the events in Pompeii's history.

State of Knowledge and Current Debates

More than 200 years of excavation at Pompeii have revealed the rich history of a vibrant community that expanded and evolved over four centuries. By the second century CE, Pompeii had become a prosperous city that had hundreds of grand residences, such as the well-known House of the Faun, House of Vettii, House of Julia Felix, and House of the Surgeon, as well as many public spaces such as *thermae* (bath houses) amphitheater, two theaters, and a *palaestra* (open area for exercise). Until recently those who studied Pompeian houses tended to focus on analyzing architectural details and styles. Rooms were identified and described with little understanding of their use by the people who lived in them. New work has sought to investigate what the houses reveal about how the spaces were used. For example, Andrew Wallace-Hadrill (1994) interprets the private spaces of luxury houses as a reflection of Roman public life where the *pater familias*, head of the household, also exerted power and control in the public spaces of business and politics.

The center of Pompeian life was the Forum where the most important social, financial, political, and business activities took place. Pompeians could relax and socialize in one of the large *thermae* in the town. There they could exercise, purchase food, get a massage, or engage in sexual activities, as evidenced from the graffiti and erotic paintings on the walls of the Suburban Baths. Manufacturers and retailers ran businesses from shops in the front of their homes that opened onto the street and displayed their saleable goods or services, such as shoes and leather work.

Pompeii was a cultural and trading center and a significant contributor to ancient Rome's increasing economic prosperity. The Campanian region was famous for its wine which was exported to Rome, southern France, Spain, and North Africa. The writer Florus tells us that the surrounding mountains were planted with vineyards and a wall painting uncovered in the *lararium* of the House of the Centenary shows Mount Vesuvius situated in a landscape covered with grapes. Pliny the Elder complained that Pompeian wines were notorious for causing headaches that could last until the following day.

Wool and textile production were another industry in Pompeii. Sheep were bred in the Vesuvius area and Pompeii was a regional center for cloth making and dyeing. Wool was processed and dyed for textiles and a cleaning service for togas was provided at the Fullery of Stephanus, excavated in 1911. However, the longstanding interpretation by Walter O. Moeller (1976) which proposed that Pompeii was the center of the wool industry was challenged by Dutch scholar Willem Jongman (1988) who argued that

Moeller's interpretation was overly influenced by his knowledge of the medieval wool trade and cloth guilds of northern Europe. Jongman suggests that the local wool trade was only small and that the cultivation and sale of crops were far more important to the local economy.

Art and architecture also provide an insight into the opulence surrounding some of its inhabitants' lifestyles. Wall paintings and portraiture in marble and bronze suggest a community with sophisticated appreciation of art, nature, and aesthetics. Pompeian wall painting was classified into the so-called Four Pompeian Styles by German art historian Augustus Mau in 1882 (Mau and Kelsey 1907). Mau attributed all the styles to foreign origins, but subsequent studies demonstrated that the distinctive styles of Pompeian wall painting were developed by Roman artists (Descœudres 1994, p. 152). One of the greatest, ongoing challenges in the recovery of Pompeian wall paintings has been their preservation. In 2013, conservators used modern technologies and scientific techniques to painstakingly repair and conserve the so-called Dionysian wall paintings in the Villa of the Mysteries to restore them to their original magnificence (Lobell 2014).

Many examples of graffiti were found on the walls of houses and shop fronts on main streets and around busy intersections. Most were political slogans and endorsements of candidates in upcoming elections. But other graffiti, such as those roughly etched onto the walls of the Gladiators' Barracks, tell us of other more personal preferences: that the "girls' heart-throb," Thracian gladiator Celadus, "fought 3 and won 3" (Cooley 2004, p. 66). Some of the gladiators will have been Samnites, descendants of Pompeii's first invaders, for they had invented a sort of war game which eventually evolved into the formal gladiatorial games of which the Romans were so fond.

During the early excavations at Pompeii, the skeletons of victims were removed from where they were found and stored in various places across the site, such at the Sarno Baths. Here they became disarticulated and the bones were mixed up. These bones can now only be studied individually rather than as complete skeletons. For a long time, scholars believed that women and children, the elderly, and the disabled were the most common victims of the eruption. This was proven incorrect by an extensive study conducted by Estelle Lazer in the 1990s. Lazer's study was based on a sample of about 300 skulls and a smaller number of bones such as skulls, teeth, arms, legs, and pelvis. Other bones that were useful for analysis were those that displayed distinctive features of trauma, such as fractures and disease. Lazer's study revealed that there were roughly equal numbers of adult males and females in the sample of victims, and they were of varying ages. She found it difficult, however, to estimate the number of children who died because very few skeletons of young children were preserved in the archaeological record.

Lazer also concluded that asphyxiation or thermal shock were the main causes of death (Lazer 2009). In their research paper, "Lethal Thermal Impact at Periphery of Pyroclastic Surges: Evidences at Pompeii," Mastrolorenzo, Petrone, Pappalardo, and Guarino, however, argue that pyroclastic surges were "the main cause of death of people" in Pompeii rather than asphyxiation (Mastrolorenzo et al. 2010).

Other scientific studies have revealed many things about the people of Pompeii, including the presence of diseases (such as malaria, tuberculosis, arthritis, and tooth decay), ages, occupations, and diets. It has even been possible to extract some mitochondrial DNA from skeletons, which in one case shows that six of the 13 individuals recovered from the House of C. Julius Polybius were "closely related" to one another (Di Bernardo et al. 2009). Analyses of the remains of foodstuffs excavated from the tables, such as bread, figs, walnuts, and pomegranates provide insights into the diets of the people of Pompeii (Berry 2007, p. 30). The contents of excavated shops, such as the Bakery of Modestus, the Bars of Asellina and Salvius, and dozens of *thermopolia* (food outlets) also revealed what the people of Pompeii were eating, drinking, and purchasing.

Scholars have long assumed Pliny the Younger's statement that Mount Vesuvius erupted on 24 August 79 CE was correct, but a graffito discovered in 2018 by Italian archaeologists

challenges this date. Scrawled in charcoal onto a wall of a house in *Regio* V, the inscription is dated (in the Roman calendar) to 16 days before the "calends" of November – which is 17 October in our modern dating system. It is now estimated that the eruption happened in the second half of October (Lidz 2019).

Future Directions

Today Pompeii bears the scars of archaeology (both legal and illegal) and tourism. In 2018, 3.5 million tourists visited Pompeii, making it one of Italy's, if not the World's, most popular tourist attractions. It is also a popular topic on the Internet, with 3D reconstructions, videos, virtual tours, and searchable maps freely available online (e.g., sites.google.com). While tourism helps support the economy of the surrounding town of twenty-first century Pompeii, one of the authorities' greatest challenges is the conservation and preservation of the site.

A Presidential Decree of the Italian Council of Ministers on 4 July 2008 declared a State of Emergency due to the hazardous conditions of the ruins. The crisis was brought to global public attention in the media with the collapse of the Gladiators Barracks in 2010 and the House of Loreius Tiburtinus in 2011. This prompted a formal agreement between the United Nations Educational, Scientific and Cultural Organization to better conserve the site (UNESCO 2012, 2013).

In January 2014, a Special Superintendency for the Archaeological Heritage of Pompeii, Herculaneum, and Stabiae was formed. In 2016, it was renamed the Superintendency of Pompeii and in 2017 became known as the Archaeological Park of Pompeii, thus adjusting to international standards for cultural institutions and sites (Pompeii 2019). The Archaeological Park of Pompeii is an autonomous body of the Ministry of Cultural Heritage and Activities and Tourism and is aimed at the preservation, conservation, and promotion of public use of the archaeological site.

The Great Pompeii Project was initiated by the Italian government in 2012 with the aim of protecting the archaeological area of Pompeii by developing a special urgent program of conservation, maintenance, and restoration. It is supported by the European Union with funding of 105 million euros between the European Regional Development Fund and the Italian government. The main areas of intervention include: reduction of the hydrogeological risk by securing the unexcavated embankments; securing the *insulae*; consolidation and restoration of masonry; consolidation and restoration of decorated surfaces; protecting buildings from weather exposure; increasing the number of areas that can be visited; and strengthening of the video-surveillance system. The project is supported by a plan for scientific and technical study aimed at diagnosis, expansion of scientific knowledge, and providing operational direction.

In 2018, to celebrate the 270th anniversary of the discovery of Pompeii, authorities announced that new excavations would begin in *Regio* V, an area positioned between the House of the Silver Wedding and the House of Marcus Lucretius Fronto, which has not been investigated since World War II. The area forms part of The Great Pompeii Project, the largest intervention which aims to stabilize around 22 ha of the unexcavated area of Pompeii over a period of 2 years, at a total cost of around 8.5 million euros. Excavations have already revealed some remarkable works of art, such as frescoes of Narcissus and Leda and the Swan in one of the houses, now called the House of Leda. There have also been proposals to use state-of-the art techniques to reexamine the existing collections and to carry out DNA tests to try to determine family relationships (Lidz 2019).

It is worth noting that the catastrophic eruption that destroyed Pompeii and surrounding areas is a recurring event. Scientists have dated the pumice deposits found beneath the material deposited by the 79 CE pyroclastic eruption of Mt Vesuvius to 1780 BCE. Mastrolorenzo, Petrone, Pappalardo, and Sheridan's research paper indicates that another major Vesuvius eruption could be imminent (Mastrolorenzo et al. 2006). This prediction should be considered when deciding the direction of future archaeological work as well as during the planning of restoration programs being undertaken in and around Pompeii.

Pompeii's discovery and excavation has enabled unique insights into a way of life centuries ago because of the effects of a devastating natural disaster. Even given the considerable amount of archaeological investigation already undertaken, there is still great potential for new knowledge to emerge, especially given the continued advances in investigative and conservation techniques.

Popular Culture and Archaeology

Melanie Coughlin Depcinski
Department of Anthropology, University of South Florida, Tampa, FL, USA

Introduction

Popular media has influenced the public view of archaeology for over a century. Before the genesis of digitally based mass media, popular culture as it related to archaeology was based on the accounts of travelers and other print-based media. In the modern age, motion pictures, television shows, print media, and video games have all served to

bring archaeology to the masses. Unwittingly, these forms of media often misrepresent the methodological and theoretical underpinnings of the field in favor of adventure and glamour. *King Solomon's* Mines (1950 and 2004), *Indiana Jones* (1981–2008), *Laura Croft*: *Tomb Raider* (2001), and the *Stargate SG-1*(1997–2007) series are just a few examples of how simplistic views of archaeology have been popularized in the mass media. These portrayals of archaeologists in action promulgate a romanticized and adventure-based view of the discipline, a view that frequently overshadows archaeology's scientific goals and practices. In addition to influencing how archaeology is viewed as a discipline, popular culture has an effect on how the public regards archaeological resources and associated geographic areas.

Definition

Archaeology as displayed in movies, television, fictional novels, and other popular media focuses on adventure and ignores the technical and practical elements of archaeological fieldwork while creating a new identity for archaeologists as adventurers and cultural connoisseurs. Additionally, these media also neglect to include the research and preparation necessary to undertake before entering the field. The analysis of data and the ethical implications of research are wholly ignored, leaving these elements of archaeology as a science a mystery to the public who consumes this image of the discipline. Though archaeologists in the field are prone to consider actual archaeological research as absent from the minds of those who produce popular forms of media, those who develop these forms of entertainment – in all actuality – rely on archaeological work for the production of stories for the interested public. Without the archaeologist, popular representations of past cultures – and the way in which they are accessed – would be produced based on pure fantasy and speculation, rather than simply lacking in detail and scientific veracity. Moreover, the many attitudes and ideals that are fueled by popular media have a direct effect on how the cultural patrimony of the world is guarded and understood. However, it is necessary to remember that archaeologists are the primary source of public discourse with the past, and ultimately the interest in these areas on the part of archaeologists is the catalyst for the emphasis on various time and regions – such as ancient Egypt, the classical Mediterranean, or the biblical Near East – in popular media (Kroshus Medina 2003).

Key Issues/Current Debates/Future Directions/Examples

Beyond representations of archaeology and uncovering the past in cinematic formats, there is now an excess of television shows that focus on popular notions of uncovering the past. In some cases, like that of the show *American Digger* on Spike TV, what is shown can hardly be called archaeology. An unknowing public may take it as such an endeavor and absorb messages that are much more harmful to the archaeological record and the image of the discipline than seeing an archaeologically based adventure film. Despite this fact, archaeology is not without hope in the public eye. As long as there have been television programs and movies for the archaeologist at heart, there have also been publications such as *National Geographic* or *Archaeology* magazine to temper fiction with fact. Thus, while many in the profession may ultimately fess up to being drawn to archaeology by films such as *The Mummy* (1932 and 1999), pop culture does more for the field than lure unsuspecting adventurers into the clutches of scientific rigor.

The placement of archaeology in such a romantic and unscientific light can elicit a trend in response that tends towards a condemnation of these representations as false or misleading (McGeough 2006). However, researchers such as Vergil E. Noble (2007) have pointed out that the way the story is told does not always change the message. Although Hollywood representations of past stories may not be entirely accurate or show the archaeologists as a treasure-hunting adventurer, the reverence and awe of the past that drives so many professionals to enter the field is

undoubtedly present. While the public may come away confused as to certain technical elements of the discipline, the basis of their desire to engage with archaeology in cinematic form is not to have a formal lesson on excavation. Rather, they are there to be entertained, and what is deemed entertaining is often a reflection of public interest rather than a choice on the part of the producer. A public interest in archaeology and the past is absolutely vital to the promulgation of the discipline beyond pure academic interest (Sabloff 1999). If people were to stop seeing the past as interesting and exciting, the drive to preserve, protect, and engage with it would ultimately diminish and with it the professional ability to act as stewards of the past (SAA Principles of Archaeological Ethics). Movies, television, video games, and even popular books by authors such as Dan Brown or Steve Berry – authors of *The Da Vinci Code* and *The Alexandria Link*, respectively – all serve to peak public interest in the past and hopefully drive people to learn more about the archaeology of their own areas or the discipline as a whole.

Also at issue here is the perception that archaeology can only happen when artifacts are excavated and removed from their context into a laboratory or museum setting. Professional issues such as curation, the acquisition of permits, and the rights of cultural groups to the protection of their ancestral heritage are not addressed in the popular media. This results in an enthusiastic public that does not fully grasp the destructive nature of archaeology or the importance of the life of the artifacts themselves. Rather than condemning filmmakers for the popularized view of archaeology they have put forth, the discipline should thank them for acting as an inspiration to so many in the field and in the public. Both the Society for American Archaeology (SAA) and the Archaeological Institute of America (AIA) have sought to do this within their respective organizations. In 1996, the SAA recognized the producers of *Star Trek: Voyager* and *Star Trek*: *Next Generation* for their portrayal of archaeology, and in 2008 the *Indiana Jones* star Harrison Ford was elected to the board of directors for the AIA and awarded for his contributions to the public presence of archaeology (Aldenderfer 1996; AIA News 2008). Furthermore, it should be taken on as professional responsibility to find ways to educate the public beyond television and movies so that they may come to know the science of archaeology and the important issues archaeologists deal with when they are not fighting to rescue the past they so eagerly strive to protect (Sabloff 1999). To this end, the AIA and many scholars in the field have worked towards addressing issues of accuracy in popular historical representations such as *Troy* (2004) or Mel Gibson's 2006 film *Apocalypto*. In order to satisfy the public's interest in history and the truth of the past, the AIA and SAA have also made an effort to disseminate scientific evaluations of popular movies and television shows (Waldbaum 2004; Dixon Renoe and Jeppson n.d.).

Though the real world of archaeology may not seem as exciting on the surface as it is in the movies, archaeologists should – and certainly do – strive to make it important and exciting in their own communities. Indeed, Jeremy Sabloff (1999) cogently illustrates how the professional structure of archaeology has prohibited the communication of archaeological practices and findings to the public in popular formats. In recent years, this disconnect between archaeologist and the public they serve has begun to shrink with the expansion of public archaeology and an ethical imperative to make research and results accessible to communities (SAA Ethics in American Archaeology Committee 1996). Professional archaeologists in the popular media are still underrepresented however and are thus inaccessible to the general population. The absence of professional archaeology from these popular formats opens the door for misinterpretation and furthers the glamorous view of archaeology through misguided interpretations of the past and a reliance on famous historical enthusiasts (Sabloff 1999). Archaeology can only benefit from a deeper involvement in the popular presentation of the subject. Only when there are real, accessible, examples to follow will the public form their opinions of archaeologists and their duties on reality rather than the archetypes transmitted through popular culture.

The representation of archaeology in popular media greatly influences the public perception of

the discipline. Although there are issues with the way archaeology and archaeologists are depicted in movies, books, and on television, the real issue lies in the general public consensus that has been fueled by these images of the archaeologist as adventurer. Many of the misconceptions that are held about archaeology and those who work in the field are not limited to a single geographical region. In his 2006 article, "Out of the Box: Popular Notions of Archaeology in Documentary Programs on Australian Television", Stephen Nichols summarizes popular misconceptions held in Australia, the United States, and Canada. With the widespread consistency of archaeologists being considered as connoisseurs of all pasts, diggers of dinosaur bones and ancient treasure, and academics with no relevance in today's world, it begs the question of how this global attitude towards archaeology developed and how those in the field can work to address these issues on a global scale.

Port of Alexandria: Underwater Archaeology

Franck Goddio and David Fabre
Institut Européen d'Archéologie Sous-Marine, Paris, France

Introduction/Definition

Founded by Alexander the Great in the western Nile Delta in 331 BCE, Alexandria developed over several centuries as a result of specific geomorphological features and the systematic development of its coastline. The Pleistocene sandstone bedrock provided a stable foundation for the construction of buildings, while also serving as a quarry. An inland lake was located behind the city, and across from it was an island. This island, named *Pharos* by the Greeks, was connected to

Alexandria early on in the Hellenistic period by means of a 1,200-m causeway or *Heptastadium* that created a dual harbor complex, with the port of *Eunostos* to the west and *Megas Limèn-Magnus Portus* (or *Portus Magnus*) to the east. The objective of the research project launched in 1992 by the *Institut Européen d'Archéologie Sous-Marine* (IEASM) in cooperation with the Supreme Council for Antiquities of Egypt (SCA) was to determine the precise ancient topography of the eastern port of Alexandria now underwater (Goddio and Darwish 1998: 1–52; Fabre and Goddio 2010). This study has included both the geodynamic research of natural and anthropic features and the analysis of the coevolution of ancient society and the coastal area of the western Nile Delta.

The scientific approach to the study of the *Portus Magnus* was designed to utilize the full range of geomorphological and archaeological data, as well as literary, epigraphic, and iconographic sources. Extensive historiographical knowledge of the accounts of the first explorers was also essential to the study. This data has provided a crucial link between the monuments from antiquity that were still visible when the early travelers' reports were written and the area under examination, which covers 400 ha of the present day eastern port (Fig. 1).

The scientific approach to the investigation of the *Portus Magnus* has taken into account the specific topography of the areas studied. However, the simple observation of the current state of the seafloor using geophysical and geological prospecting instruments also failed to provide full insight into the ancient topography. One effective method of locating underwater archaeological ruins covered in sediment was to use sensitive nuclear magnetic resonance magnetometers to create a very high-definition magnetic map. This indicates the location of the buried archaeological ruins by continuously measuring the absolute value of the magnetic field, with a sensitivity of about 1/100 gamma. An electronic image of the seafloor has also been created by means of scanning with a side-scan sonar and, more recently, a multi-beam sonar, which has revealed items protruding from the sediment.

The results of this work demonstrate that the sites were subject to both long-term subsidence of

Port of Alexandria: Underwater Archaeology, Fig. 1 The ancient topography of the *Portus Magnus* of Alexandria. (Photo: Franck Goddio ©Franck Goddio/ Hilti Foundation)

the land that commonly affects this section of the southeastern basin of the Mediterranean as well as short-term cataclysmic sediment failure. These factors, which may have operated independently or together, would have caused considerable destruction and explain the submergence of the *Portus Magnus* as well as other large parts of the Canopic region (Goddio 2007; Stanley 2007). All of the evidence has shown that regular subsidence and the rising sea level – observed since ancient times – contributed significantly to the submergence of the *Portus Magnus*. It is generally acknowledged that the sea level in Alexandria has risen by 1–1.5 m, and the land level has dropped by 5–6 m over the last 2,000 years. The southern coast of the eastern Mediterranean has also been subject to various forms of tectonic movement due to the subduction of the African plate under the Anatolian plate. Ancient texts give accounts of earthquakes and tsunamis affecting the region, especially the tsunami of 21 July 365, which affected southeastern Mediterranean coasts, and an earthquake in the mid-eighth century.

Key Issues/Current Debates

An Overview of the Hellenistic and Roman Topography of Alexandria's *Portus Magnus*: Texts Versus Archaeology

While geophysical prospection in the Port of Alexandria and subsequent underwater excavations has failed to reveal the splendor of the palaces of Alexandria, they have generated excellent cartographic details of the eastern port and its surroundings. The research has allowed the contours of the former land surface to be traced with a certain degree of accuracy and in some cases has provided information on the structures and buildings which once stood near the palaces, such as the royal ports, the *Poseidium* peninsula, and the island of *Antirhodos*, as well as the *Basileia* – a seafront palace complex containing a series of government buildings and cultural institutions. The study of the harbors has focused on determining their depths and sedimentation type, identifying shipwrecks, and tracing the plan of the docks (Figs. 2 and 3). The numerous architectural elements

Port of Alexandria: Underwater Archaeology, Fig. 2 Port structures assembled from piles and wood planks that support a structure made of limestone blocks, PF sector, northeastern of the Poseidium peninsula. (Drawing: Patrice Sandrin ©Franck Goddio/Hilti Foundation)

P

covering the palace area were identified and studied, and limited excavations were carried out to determine the timeline of the development, abandonment, and destruction of the sites. The layout of the ports turns out to be more technically coherent than previously believed.

More precisely, two channels leading to the large port have been mapped. The main channel, toward the middle of the harbor, was bordered to the west by a large submerged rock. The narrower minor channel allowed ships to pass between this rock and the island of Pharos. The famous lighthouse must have stood nearby. Considering the topographical and geological results along with the literary evidence, and in the absence of archaeological proof showing another position, it is reasonable to posit at this point that the lighthouse was located on the rock situated between the two channels. Nothing visible remains today of this prestigious monument that was a wonder of its day. Its remains are probably hidden by the enormous mass of the current western breakwater, which links Fort Qaitbey to the great central rock, now submerged and mostly covered by the blocks of the modern structure (Goddio et al. Forthcoming, *contra* Empereur 1998 for which the lighthouse was situated on the site of the medieval Fort Qaitbey).

Recent archaeological work has identified built-up areas to the west of the "royal port" (in the central area of the Bay of Alexandria), highlighting the complexity of the *Portus Magnus'* infrastructure. While it remains unclear as to exactly how such structures were organized, the results shed light on the navigable routes inside the *Portus Magnus*, confirming that it was "wonderfully concealed" (Strabo, 17.28; Charvet 1997). The eastern part of the great port is, in fact, delimited by a large stretch of land, now underwater, which formed part of the ancient Cape Lochias. Appreciably wider and extending over 450 m west-northwest of present day Cape Silsileh, it provided considerable natural protection for the *Portus Magnus*.

A very sheltered port was established in Cape Lochias, with two docks and a surface area of approximately 7 ha. Jetties, quays, and seawalls combined to form a well-concealed port almost inserted into Cape Lochias. Since the large central reef had to be navigated to enter the port, only rowing boats like galleys would have been able to enter easily. The discoveries here correspond to ancient texts. According to Strabo, "Above these buildings (in Cape Lochias) lies a concealed man-made port, private property of the kings" (Strabo, 17.1.6-10; Charvet 1997). The author of *The Alexandrian War* wrote: "This area of the city (where Caesar was entrenched) contained a small part of the royal palace where he himself had been brought to lodge on arrival, and the theater, adjacent to the palace, which served as a citadel and provided access to the port and the royal shipyards" (*Bellum Alexandrinum*, 1; Andrieu 1954).

A large port was established between the southwestern jetty of the inner port and the Poseidium peninsula, measuring approximately 15 ha. The remains of a temple from the Roman period have been excavated where the peninsula meets the ancient shoreline. At the end of a wall of the peninsula, extending toward the center of a port basin, excavations have revealed foundations dating from the end of the first century BCE and redevelopments from the period of the Antonines. The identity of the ruins is not certain, but we know, thanks to Strabo, that Marcus Antonius built the *Timonium*, a small palace retreat at the end of a wall of the Poseidium. He wanted to retreat there and live in seclusion after his defeat at Actium by his rival Octavian. Could the ruins from the end of the Ptolemaic period be those of the famous Roman general's retreat? Excavations in progress may reveal this.

The island of *Antirhodos*, 350 m long by 70 m wide, is located off the southwestern tip of the *Poseidium* peninsula and may be divided into three sections. The main section, with a southeast to northeast orientation, is aligned with the seawall and the pier extending from the tip of the peninsula and lies parallel to the ancient coast. Research has shown that this island had probably been developed before the founding of Alexandria (cf. *infra*) and that extensive work was executed there later, toward the middle of the third century BCE until the Roman period. A large seawall protrudes from the northwestern end of the island, 340 m long by 30 m wide, forming a second section. Recent fieldwork conducted on this area has confirmed the presence of large size buildings characterized by limestone blocks, fragments of wall covering, mosaics, and friezes. The information indicates the collapse of a building, probably in correspondence with the destruction of the eastern part of *Antirhodos*. This is the same area from which the statue of a priest carrying a Canopic jar (Goddio and Fabre 2008: 161) was found along with sphinxes (Fig. 4). Among these finds was a statue of Ptolemy XII, the father of Cleopatra VII (Goddio and Fabre 2008: 356–357), suggesting the site of a temple dedicated to Isis. At the end of the third section, oriented northwest to southeast, a jetty built from limestone blocks protrudes northeast, forming with the island a small haven fully sheltered from swells and waves, which may correspond to the "small port" described by Strabo: "... private property of the kings, as is *Antirhodos*, the island located before the man-made port, containing a royal palace and a small port" (Strabo, 17.1.6-10; Charvet 1997). Here, the remains of a ship lie some 5 m deep and spread over a surface of about 350 sqm. The ship seems to have been free of any cargo. Nevertheless, the items found on board and in the sealing layer above the wreck, the details of the ship's architecture, and radiocarbon dating results suggest that the ship sank sometime between the end of the first century BCE and the first century CE. Its approximate dimensions (30–31 × 10–11 m) – representing a coefficient of elongation of about 2.7 – correspond to the dimensions of commercial ships of the Roman period (Sandrin et al. 2012).

The ruins of quays and piers were also identified during prospecting on the "ancient coast" (Fig. 5). This alone shows that nineteenth- and twentieth-century reclamation work encroaching on the sea with landfills did not entirely conceal the area that subsidence and land collapse had previously submerged. Visible along the entire eastern part of the *Portus Magnus*, this ancient

Port of Alexandria: Underwater Archaeology, Fig. 4 Priest bearing in his veiled hands an Osiris-Canopus jar. Roman period. Granodiorite. H. 122 cm. (Photo: Christoph Gerigk ©Franck Goddio/Hilti Foundation)

coast is sometimes paved and contains numerous architectural remains and beautiful remnants of statuary, among which was a colossal head of Caesarion (Goddio and Fabre 2008: 357).

The research carried out in the western part of the *Portus Magnus* reveals the complex organization of the Port of Alexandria. After describing the

Port of Alexandria: Underwater Archaeology, Fig. 5 Ruins of quays or esplanade identified during prospecting on the "ancient coast." (Photo: Christoph Gerigk ©Franck Goddio/Hilti Foundation

royal quarter and port and moving from east to west, Strabo continues to examine this area: "Next comes the *Caesareum*, then the *Emporium* and the warehouses followed by the arsenals, extending as far as the *Heptastadium*" (Strabo, 17.50.9; Charvet 1997). Facing the *Heptastadium*, a port protected this long causeway (Fabre and Goddio 2010). It featured basins ideally suited to receive ships waiting to go from the eastern port to the western port that gave access to Egyptian domestic traffic. Indeed, according to the texts (Strabo, 17.1.6; Caesar, *Bellum Civile*, 3.312), two openings were constructed in this seawall and controlled by forts, allowing passage from one port to another.

Development and Operation of the Port

The discoveries in the eastern Bay of Alexandria show that the entire port infrastructure was

designed to optimize the natural environment. Nevertheless, beginning in the Hellenistic period, harbor construction and urban development resulted in dramatic changes to the coastline. This forces us to consider the logic behind transforming an enclosed natural bay into a series of harbors.

Maritime dynamics also hint at the historical workings of the *Portus Magnus*. The map of the submerged port structures in the eastern port of Alexandria suggests a vast bay surrounded by a group of similarly sized harbors. J.-Ph. Goiran correctly notes: "Due to the specific organization of the bay, initially too vast to provide natural shelter, a group of small harbors was needed along the far end of the bay [. . .]. The purpose of these was to break up the coastline as seen in modern marinas" (Goiran 2001: 140). Alexandria's *Portus Magnus* benefited from its specific geography. The archaeological structures found are cut out of the substrate or constructed in the form of straight or curved seawalls. Similarly, the extremely developed coastline has been somewhat artificially extended. Diodorus of Sicily notes: "They [Alexander's successors] enhanced it, some building magnificent palaces, others constructing arsenals and ports, others adding religious monuments and magnificent buildings, so that in the eyes of most people it was the first or second city of the inhabited world" (Diod. Sic., 1.50.7; Vernière 1993). The Romans more than likely optimized the structures of the port and made proactive adjustments to what the Ptolemies had initiated.

It is not completely possible to establish a convincing parallel between the eastern port of Alexandria and the classical port models, such as the ports with merging lagoons or *cothon*-type port. At most, very general similarities may be found with the Port of Tyre (Bernand 1998: 47; Marriner et al. 2008). Yet the Port of Alexandria forms part of a series of major port developments which began in the sixth century BCE and may be attributed to maritime projects and ambitions of great tyrants. The Greek approach was applied to the Bay of Alexandria, by which a man-made port was created or a natural port was enlarged using jetties to provide shelter from the winds, to facilitate landing and to protect the ships. The jetties were often curved in such a manner as to form a port. In some cases, an islet in the bay was used as the base for a single large seawall: Alexandria's *Heptastadium* is the best preserved example of this. By Greek standards, these structures alone constituted a "man-made port." But there were also ports dug by hand, at least in the Hellenistic period. Such was the case, in Alexandria, of the port known as the "box" (*kibôtos*) in the western harbor (Fraser 1972: n. 182; Tkaczow 1993: 58 n. 6; McKenzie 2007: 176).

Pharaonic Egypt does not seem to have had "constructed" ports on its shores. At most there would have been landing piers and/or anchorage points (Fabre 2004: 19–35), with the exception of the ports in coastal lakes of the Nile Delta. Does this mean that the Port of Alexandria was developed *ex nihilo*? A number of converging factors suggest that the Bay of Alexandria was developed before the arrival of Alexander. The wooden port structures (quays and jetties) discovered in the axis of the eastern – and main – section of the island of *Antirhodos* have been dated as pre-Ptolemaic (Goddio and Darwish 1998: 31). The data should be correlated with recent analyses of the lead contained in the sedimentary archives for the harbors in the eastern Bay of Alexandria, which contradicts the notion that Alexandria was constructed *ex nihilo* (Goiran 2001: 223–224; Véron et al. 2006; Stanley and Landau 2010). These results corroborate certain accounts in the ancient texts, which state that the Bay of Alexandria offered an anchorage point well known to sailors (Homer, *Od*. 4.354-69).

Alexandria obeyed an economic and political logic that had gradually developed over the centuries to become "the largest *emporium* of the inhabited world" (Strabo, 17.1.13; Charvet 1997). Alexandria inherited the administrative and economic structures of Thonis-Heracleion (Pseudo-Aristotle, *Economics*, 2.33e). This locality was the border crossing, customs post, and *emporium* through which Greek imports passed on their way to the trading posts of Naukratis

(Fabre 2008). Due to its population size and its activities, Alexandria quickly attracted a large share of Mediterranean and Eritrean trade. Alexandria was a center of eastern navigation in the Hellenistic period, and its commerce benefited from the state organization of the Ptolemaic economy. Later, during the Roman period, Egyptian grain shipped from Alexandria was used as a genuine political weapon by emperors and claimants to the imperial throne alike. This would have required substantial port infrastructure, and thus the port was well equipped with harbors, quays, warehouses, and water supply points (Fabre and Goddio 2010) (Fig. 5).

These zones of the *emporium* of Alexandria, as well as the royal ports, military ports, and shipyards were designed as places of transit and transfer and are distinguished by their technical, political, and economic dimensions. The research currently being completed should provide clues as to the layout of these areas crossed by ancient ships. We should also gain insight into the cultural organization or implicit hierarchies in the *Portus Magnus*. From a technical viewpoint, the results of topographical work in the *Portus Magnus* of Alexandria raise questions regarding the port layout while also taking navigating conditions (winds and swells) and the types of vessels accommodated (sailing ships or row boats) into consideration. From a theoretical viewpoint, the zones of the eastern port are at the core of more general questions regarding the major political and economic intermediary players in the organization, regulation, and administrative and legal structures that served to define the harbor and its integration into the city.

Portable Art Recording Methods

Gilles Tosello[1] and Valentín Villaverde[2]
[1]Centre de Recherche et d'Etude pour l'Art Préhistorique (CREAP), Toulouse, France
[2]Departamento de Prehistoria y Arqueología, Universitat de València, Valencia, Spain

Introduction

Although much less well known than rock or cave art, Paleolithic portable art is comprised of graphic and symbolic manifestations represented on objects and on portable raw materials in contrast with parietal or wall art, which is, by definition, "immobile"), which were left by human groups during the Upper Paleolithic period (between 45,000 cal BP and 15,000 cal BP in Europe). The first European portable art was recovered in the 1860s, very early in the history of prehistoric archaeology. Some pieces, such as the mammoth engraved on ivory at La Madeleine (Dordogne, France), played a determining role in the debate on the existence of an "antediluvian" art. For nearly a century, discoveries proceeded at a steady pace, enriching public and private collections; however, the excavation methods often practiced at that time rarely took into account the archaeological contexts of the objects. Documentation is often reduced to the object itself and any new study must begin with a search of the archives regarding the site or the excavator, whenever these are available.

Although the total number of pieces discovered in Europe is unknown (there is no international data base on this topic), it can be estimated to be in the tens of thousands with concentrations at sites in the southwest of France, Spain and northern Italy, central Germany, Slovakia, and the Czech Republic. The distribution of sites having yielded portable art is much greater than that of cave art. However, the number of pieces per site varies considerably; there are sometimes isolated pieces such as at Etiolles (Essonne, France) (Fritz and Tosello 2011), a set of several dozen *decorated* objects such as at Altamira (Cantabria, Spain) (Barandiaran Maestu 1973), Romanelli (Puglia, Italy), and Duruthy (Landes, France), and up to a corpus of several thousand objects such as those found in deposits in El Parpalló (Valencia, Spain) (Villaverde 1994), Gönnersdorf (Rhineland-Palatinate, Germany) (Bosinski and Fischer 1974; Bosinski et al. 2001; Bosinski 2008), or La Marche (Vienne, France) (Pales and Tassin 1969).

The materials are of great diversity: bone, ivory, antler, shells, and marine fossils, including also limestone, shale, and sandstone. The term portable art applies to objects as diverse as a reindeer antler spear point decorated with crossed line patterns, a flat bone pierced and carved in the

Portable Art Recording Methods, Fig. 1 Limeuil (Dordogne, France). Perforated baton decorated with three reindeer, a salmon, and a horse (coll. Musée d'Archéologie Nationale). (Photos G. Tosello)

shape of a horse head, a statuette of a woman in soapstone, or a limestone slab sculptured into a bison. Typology, combined with experimentations have made it possible to classify these objects into three main categories (Leroi-Gourhan 1965).

The first category includes weapons, domestic tools, and all the objects for which their function determines the morphology. Thus, a perforated baton has a shaft, more or less cylindrical, and an expanded top with a perforation. Consequently, the decorations fit these constraints (Figs. 1, 2, and 3).

A second category includes set of ornaments in the broadest sense of the term. The presence of a suspension system (e.g., a pierced hole) is the common attribute to group together seashells, animal teeth, small flat bones cutout (in disc form, zoomorphic silhouette), fragments of rare materials (lignite, amber, fossil tooth), animal or human statuettes or figurives, which are thought to have adorned the body or clothing.

Finally, the third category consists of bones and stones of all sizes, which are engraved or carved into three dimensions. At some sites engraved stones, commonly called "plaquettes" number in the hundreds, even thousands, and whose social functions remain enigmatic (Pales and Tassin 1969; Bosinski and Fischer 1974; Villaverde 1994; Tosello 2003).

However, this classification should be regarded as only a first approach. There are many pieces of portable art that are "unclassifiable," especially those which were transformed or reused, and not even considering certain objects or weapons

Portable Art Recording Methods, Fig. 2 Limeuil (Dordogne, France). Perforated baton in reindeer autler; from *top* to *bottom*, details of two reindeer, a horse, and a salmon (coll. Musée d'Archéologie Nationale). (Photos G. Tosello)

whose actual function has not been established with certainty. The diversity and difficulty of classifying such archaeological materials show that above all the artistic and symbolic practices of these prehistoric hunter-gathers permeated their activities.

Definition

The organic or inorganic (i.e., mineral) nature of the raw material has important consequences for the study of the objects and the techniques used. Contrary to what one might think, stone materials (limestone, sandstone, schist) are often in poorer condition than organic materials. Indeed, the latter, and bone in particular, because of its fibrous and compact structure, offer a high degree of

Portable Art Recording Methods, Fig. 5 Theoretical scenario of a "cycle" of an engraving which helps explain the high level of fracturing that affects the engraved plaguettes in Europe, particularly in the Upper Magdalenian. (G. Tosello scheme based on site data from Limeuil)

conservation of engravings and traces from shaping (Fritz 1999a). By contrast, the surfaces of sedimentary stones have often suffered from chemical damage or carbonate deposits during their long deposition within archaeological layers. The engraved features, clearly legible in prehistoric times, are now weathered and difficult to read; only the use of lateral lighting close to the rock can reveal them. Painted objects are very rare, because the colors are not retained; nevertheless, some pieces with traces of pigment, or even identifiable figures, have survived and prove that portable art was also colorful (Villaverde 1994) (Fig. 4).

Portable art is affected by a very high level of fragmentation; whole pieces are rare, because they suffered conditions of burial in the ground or they were damaged during the excavation: some were intentionally damaged by prehistoric peoples.

Whatever the nature of the raw material, one of the first stages of research (if not the first) is to estimate the state of conservation of the object, determining whether it is "complete" (or almost) and if this is not the case, identifying the origin or origins of fragmentation. While studying pieces from old excavations, it is important to ensure that there are no other fragments of that same piece to be studied. This reconstruction of the pieces is essential when studying engraved or sculptured stone materials, plaquettes, slabs, and blocks. It can often complete figures, which will confirm or modify the zoological identification, for example. By observing the nature of the fractures (modern or ancient), we can begin to reconstruct the life cycle of the object from its origin to its current state (Fig. 5).

The next step in the research is to establish a graphic copy (or "relevé"). All of the traces observed on a surface must be reproduced objectively. The tracing phase is critical for subsequent syntheses of observations, such as the themes depicted; besides being a document for analysis, the tracing becomes a substitute for the object, particularly at the time of publication. The different readings of the same object made by different researchers generally show minor variations, which may sometimes be significant, showing that objectivity remains an elusive goal.

Tracing techniques fall into two categories: contact and non-contact tracing techniques. Known for a long time, contact tracing techniques are intuitive and easy to implement. A very fine and perfectly translucent plastic film (of the polythene variety) is placed over the surface; a raking light, moved from time to time as work progresses, can help identify engravings, or any other information, which are then transferred onto the film using thin-tipped markers. This technique offers some advantages: it is cheap, easy to use, and very adaptable on rough stone surfaces and poses little danger to the original.

When the dimensions of the object are small (only a few cm^2), direct transfer becomes impossible, especially if the incisions are very thin (Fig. 6). It then becomes necessary to work on photographic enlargements; one puts a transparent film on the printed photo, and all that is needed is to replicate the rendition of the photo, constantly checking against the original.

The difference between the original engraving and the photo transfer on a different scale is a mental challenge. A variant of this technique is

to trace the lines on a photo of the piece displayed on the computer screen, with the aid of graphics software. In cases where the engravings are not located on a flat surface but on three-dimensional surfaces, it is necessary to test which method is best suited, for example, through a deconstruction of the piece see (Fig. 3). When the engravings are very dense, the process of selecting layers for tracing can isolate each one of them (Fig. 7).

Each of these procedures presents specific advantages: drawing directly on the film covering the object allows, through the reproduction of the same lines, a very close approximation of the prehistoric engraver's gestures. On the other hand, the magnification of engravings through photography (printed or displayed on the screen) provides a stable base for the copy, which thus avoids a sometimes too ephemeral observation of the original piece. On miniature works, the enlargement can reveal minutiae that are almost imperceptible to the naked eye.

When it comes to publication, the tracing plays a major role: it represents the synthesis of the decipherment done by the researcher that is

Portable Art Recording Methods, Fig. 7 Gourdan Cave (Haute-Garonne, France). Engraved plaquette in schist No. 47264. Complete tracing of the engraved sen face and selective tracings of three animal heads in the order of superposition: reindeer, horse, and aurochs (?). (Tracings C. Fritz)

his/her interpretation of the object. The temptation is often great to reproduce as much information as possible (differential readability of the engravings, state of the surface, natural cracks in the rock, traces of shaping, concretions, etc.) which has led in the past to codification charts inspired by geology or cartography (Delluc and Delluc 1984). In our opinion, the use of complex graphic charts should be reduced because it only complicates the reader's task of "decoding" the published tracing. It should focus on the anthropogenic aspects of these objects, which in our eyes is their major interest.

Photography is an indispensable tool in any research on portable Paleolithic art. A long and delicate operation, photographing engravings is performed like deciphering, with a raking light, or of minimum incidence, applied closely. The photographic shot is important as it often provides the opportunity, through the search for optimal lighting, to confirm or reject a hypothetical reading. Photography is thus fully involved in the progress of the analysis while providing a part of the iconography.

For publication, only the photos have the power to evoke in every detail the appearance of decorated surfaces; this is an important point because if the graphic tracings seek to comprehend and try to make sense of documents, photography undoubtedly gives a more objective vision. Conversely, the publication of portable art photos, particularly of engraved plaquettes without their tracing, is an error in method and in communication (Chollot 1964); generally the reader cannot successfully isolate the figures or motifs mentioned in the text. Ideally, each piece of portable Paleolithic art should be illustrated by one or more tracings accompanied by one or more photographs to enable the reader to find how the photos and the tracings can be correlated (Figs. 8, 9, 10). The main obstacle is of course the cost of printing, especially when there are many pieces.

In this case, we must focus on publishing the most comprehensive record of the corpus (Sieveking 1987; Villaverde 1994; Tosello 2003)

Portable Art Recording Methods, Fig. 8 La Madeleine (Dordogne, France). Engraved slab in limestone. (Photo G. Tosello/coll. Musée d'Archéologie Nationale)

and avoid publishing only the pieces deemed "major" or which concern specific topics (see, e.g., at La Marche, felines and bears: Pales and Tassin 1969) which gives a truncated depiction of the site's corpus.

When the studied objects have preserved traces of paint (associated or not associated with the engraving), imaging processing techniques that are commonly used for rock art, provide an important contribution to the tracing work.

Key Issues/Current Debates/Future Directions/Examples

Since the late 1980s, the constant improvement in the performance of optical observation instruments (binocular magnifying lens, microscopes) has led to dramatic advances in the precision of

Portable Art Recording Methods, Fig. 9 La Madeleine (Dordogne, France). Tracing of the engraved limestone slab. (G. Tosello Tracing)

information, opening new avenues of interpretation (D'Errico 1995).

On bone, ivory, or antler, the observation of drawings by scanning electron microscopy (SEM) has revealed a rich source of information (Fritz 1999a). The SEM technique involves taking impressions using silicones; the resin replica, obtained from the silicon mold, is covered by a very thin film of gold or carbon to improve the electrical conductivity. Observation by SEM, even at low magnification (× 20 × 50), reveals microscopic marks (*stigmates*) left by flint tools at the base of the incisions, some of which are invisible to the naked eye (Fritz 1999b). These marks may contain mechanical information, such as the direction of movement of the tool, the inclination of the active part relative to the surface of the object, and the number of passes made by the tool in the incision. The study of the engravings can also describe the engraver's hand, to evaluate their skill or clumsiness (Fig. 11). Multiple analyses of pieces from the same archaeological layer and also from contemporary sites has helped identify local and regional "know-how", and the existence of experienced engravers and "apprentices", which also brings up the question of how technical knowledge was transmitted in the traditions of these societies.

Portable Art Recording Methods, Fig. 10 Parpalló Cave (Valencia, Spain). Plaquette No. 20044. Photo and tracing of the motifs; a horse, three aurochs, an ibex, and various signs from the Upper Magdalenian period. (Photo and tracing V. Villaverde)

Portable Art Recording Methods, Fig. 11 The contribution of microscopic analysis to study engravings on bone. Various technical features stigmas observed at high magnification can help reproduce the direction of movement of the tool and the number of passes of the tool in the engravings or the chronology of superpositions, especially when the object is miniature (2.9 cm for this engraved bone, Arancou, Pyrenees Atlantiques, France; micrographs C. Fritz coll. MNP)

Over the past 15 years, three-dimensional technologies have been used to research prehistoric parietal and portable art. The results obtained in caves have opened up the possibility for the reconstitution of decorated objects in 3D. 3D recording of an object with fine engravings is no longer an insurmountable obstacle, but does remain a major challenge; in fact, the fineness of the engravings (often submillimeter) often approaches or exceeds the maximum resolution for 3D laser scanners. Other solutions such as microtopography exist, which is a complex system of analysis and 3D restoration based on the use of a confocal microscope (Melard 2010). The resulting images are of very high precision (up to 0.1 μm), which enables the visualization of engravings and their relative chronology, thanks to the tridimensional restitution of their triangulation. The main obstacles to microtopography remain its limitations as to the scope of analysis (20 cm diameter); it requires the object to be moved to the laboratory and extends the length of data acquisition, which can take as long as several hours for a small surface.

Thanks to their high resolution, the 3D readings of engraved surfaces make it possible to obtain measures of the depth of incisions at the microscopic level, allowing the resolution of complex superimpositions of engravings (Güth 2012). On engraved plaquettes that were often reused, we can thus determine the relative chronology of different themes and compositions.

However, these methods are constantly changing, just like the processing power of computers. Similarly for digital photography, applications in archaeology continue to diversify. Among them, photogrammetry (a long standing technique used particularly in cartography and architecture) is experiencing a revival, which is particularly promising for the study of portable art. High-definition shots of the object are taken from different angles, with overlapping margins, thus forming a mosaic, from which it is possible to generate a point cloud, and then a 3D model that correlates to the photos. So, for the piece thus reproduced, it is possible to vary the lighting, zoom in, and view the details. Together, these operations can be done using free or inexpensive software, which is obviously a huge advantage for the student or researcher. For museography, the quality of the 3D photo documentation meets the needs of broadcast media and avoids unnecessary handling of original pieces.

The beginning of our third millennium is marked by a constant and dramatic evolution in techniques for analysis and restoration in all fields of science and communication. It is difficult to predict what the recording methods and study of Paleolithic portable art will involve in the near future. Because it approximates human vision in three dimensions and meets the challenges posed by prehistoric decorated objects, we believe that 3D technology (without knowing in what form (s) exactly) will become more commonly used; traditional recording or tracing techniques will gradually disappear, and online publications will increase the quantity and quality of iconography, offering the Internet user the possibility to manipulate the object virtually, offering sequences for animation or modelling, etc.

However, make no mistake: despite the advantages offered by this technology, these high-tech devices are yet another supplementary tool for the researcher and will not replace direct observation of original pieces, which remains the foundation for research.

Portuguese Faience and Historical Archaeology

Tânia Manuel Casimiro
Departamento de História Faculdade de Ciências Sociais e Humanas, Instituto de Arqueologia e Paleociências da Universidade Nova de Lisboa, Lisbon, Portugal

Introduction

Portuguese faiança or faience (majolica) can be found in colonial contexts in those parts of the New World, Northern Europe, and the coastal ports of Africa and Asia, where Portuguese goods were traded.

Until quite recently this ware was misinterpreted and classified as either Dutch or Italian ceramics in Europe and as the Spanish ceramic-type "Ichetucknee Blue on White" in the New World. Recent LA-ICP-MS (laser ablation inductively coupled plasma mass spectrometry) analyzes evidence that some of these ceramics were produced in Portugal (Casimiro et al. Forthcoming). The lack of publications concerning Portuguese ceramics published in other languages rather than Portuguese delayed for many years the correct identification of Portuguese faience (Casimiro 2011a).

There were two types of production in post-Medieval times. Between the 1550s and the late 1700s, it was produced in workshops. Starting in the 1760s, it began to be produced in factories. This entry focuses exclusively on faience, made in workshops in three different production centers: Lisbon, Coimbra, and Vila Nova (Fig. 1).

Definition

Portuguese faience is a soft-bodied, light buff- or pinkish-paste earthenware covered with a tin-based, lead glaze and normally decorated painted in blue or in blue and an additional color.

Portuguese Faience and Historical Archaeology, Fig. 1 Map of Portugal with the places mentioned in the text

Key Issues/Current Debates/Examples

Shapes and Function

Form variation is limited for Portuguese faience from the sixteenth to late eighteenth century. The variability was essentially in the decoration. Plates and bowls are clearly the most common shape, followed by bottles.

Faience objects would serve fundamentally at the table, for personal hygiene, and in pharmacies, plates and bowls being the most abundant. In the second half of the seventeenth century, archaeological records show that many vessels with the same decoration appear together, sometimes as complete table sets. Bowls, plates, and platters exhibit similar decorations and were certainly used together at the table during meals.

However, there are certain vessels that due to its physic and decorative attributes were not designed for their use in daily activities but as household ornaments. The objects found abroad, especially in Northern Europe or in English colonies are always of a finer quality and would certainly serve display purposes.

The 1572 potters' regulations register the production of many forms such as cylindrical pharmacy jars, plates of diverse sizes, pots, and jars. Other shapes, not mentioned in the document, are however known such as plates, bowls, tureens, tea pots, chargers, basins, pots, jars, bottles, boxes, lids, handled bowls, cups, chamber pots, holy water stoups, barbers bowls, spice containers, pitchers, aquamaniles, inkstands, figurines, funnels, candlesticks, and pharmacy pots discovered in archaeological contexts (Casimiro 2011a: 129).

Decorative Grammar

One of the most important characteristics of Portuguese faience is its decoration, reflecting the consumer tastes in Portuguese and European societies. Although some decorations and decorative techniques can be considered to be exclusive to each production center, in general, all three tended to use the same designs.

Portuguese Faience and Historical Archaeology, Fig. 2 Portuguese faience plate found in Carrickfergus. (Drawn by T. Casimiro)

Foreign influences, especially from Spain and Italy, can be seen from the beginning. The first faiences were clearly an imitation of Sevillian majolicas, especially the plain white plates and carinated bowls known as Columbia Plain. This imitation was so good that until quite recently the Portuguese products had been identified as Spanish (Barbosa et al. 2008). Decorative influences from Spain can be seen in designs that include small spirals inside geometric panels.

Italian influences came from Montelupo, Liguria, and Deruta, with the introduction of mythological images such as Venus and Fortunes presented as central plate designs. In the mid-seventeenth century, lace decoration started to appear. It has yet to be determined if this was a Portuguese creation or if it was inspired by the peacock feathers used to decorate Italian majolica in the late sixteenth century (Calado 2005).

The most significant foreign influences came from China (Fig. 2) through Portuguese maritime trade with the Far East. Chinese porcelain occupied an important role in Portuguese domestic environments, not only in palaces and convents, but also in more modest homes (e.g., Casimiro 2011b).

Lisbon's potters knew that Chinese Wanli patterns were much desired in Europe. In the 1619 *Corpus Christi* festival, potters in Lisbon presented faience vases in perfect imitation of Chinese porcelain (Calado 2005).

It is not known exactly when Portuguese potters started to use Chinese motifs, but it is believed to have been within the last two decades of the sixteenth century (Casimiro 2011a). One of the most significant decorative patterns is the division of the plate rim into panels, each filled with chrysanthemums and fruits, such as peaches and pomegranates, typical of coeval Kraak porcelain.

Around 1610, one of the most typical decorations of faience appeared: the *aranhões* or "big spiders." In Chinese porcelain, artemisia leaves, fans, gourds, sounding stones, and paper rolls were always surrounded by strings ending in tassels. These became key elements of Portuguese *aranhões*, which changed their original meaning and adapted them to a new European style. Other decorations of Chinese influence were also used, such as the beads or *desenho miúdo* (fine drawn) (Calado 1992).

Noble and wealthy families in Portugal and in other parts of Europe frequently requested faience vessels decorated with their respective coat of arms. These particular vessels were symbols of social status both in Portugal and elsewhere.

Chinese and European influences coexisted in Portuguese faience production.

In addition to the display of foreign influences, faience presents decorations that were developed by Portuguese potters, such as the numerous floral designs used essentially from 1635 onwards (Fig. 3). This seems to be the case with the garlands decorating plate rims, known as "baroque strip." Ferns and large leaves were also used to decorate faience plates and bowls up until the end of the seventeenth century (Fig. 4).

Production Centers

Lisbon

Lisbon was the first city in Portugal where faience production started in mid-sixteenth century, with

Portuguese Faience and Historical Archaeology, Fig. 4 Portuguese faience from Silves. (Photo by T. Casimiro)

workshops in the Santos-o-Velho and Santa Catarina areas (Carmona and Santos 2005).

Archaeological investigations have uncovered a half-dozen workshop sites, namely, in Rua de Buenos Aires, Largo de Santos, Largo de Jesus, Tercenas, Rua das Madres, and Museu Nacional de Arte Antiga. In 1672 there were 11 workshops in the Santos-o-Velho area (Mangucci 1996; Sebastian 2010).

Lisbon's fine-quality faience has a light buff fabric, while low-grade faience tends to have a pinkish one. In both cases, it is fairly homogenous and compact, and the number of inclusions is rather small.

The thick enamel is of excellent quality, indicating a high percentage of tin oxide in the glaze. There are some examples, however, with low-quality enamels, obviously made for domestic consumption, since rarely are they found in overseas contexts.

The percentage of mineral oxides used in the preparation of colors was probably a little less than in Coimbra or Vila Nova (discussed below) since the fired colors are lighter than in those centers. However, a vessel made in Lisbon can present different shades of blue.

Coimbra

The earliest document mentioning faience production in Coimbra dates to 1608, when Pedro Fernandes receives a letter allowing him to produce white pottery from Talavera (*malga branca de Talaveira*), although probably this was already in production for some years at this time (Carvalho 1921: 125).

The craft was well organized in the potters' quarter and had other ordinances besides the one indicating that no craftsmen, including potters, could open a workshop without a proper, lifetime license from the municipal council, signed by the craft's judges (Carvalho 1921:120).

In Coimbra, ceramic fabrics are pinkish or reddish, resulting from the low quality of local white clay, compelling potters to add red clays in order to strengthen fired vessels. Inclusions are very frequent with the existence of quartz and ceramic grog. The enamel presents a low percentage of tin oxide, making it thinner and less white than in Lisbon. Coimbra's blue decoration is darker and with fewer shades than the blues of Lisbon and Vila Nova. No evidence of the use of yellow has been found in the workshop excavations, although there are some investigators who believe that the yellow used in Coimbra should be darker, almost orange (Pais et al. 2007).

Vila Nova

The first reference to a kiln in this area dates to 1605, when Cristovão Fonseca sells to Manuel Gonçalves a house and a potter's kiln (Leão

1999). In 2000, an excavation exposed the remains of a workshop dating to the second half of the seventeenth century. They included a kiln, a dumpster, tanks, and an area to grind the clay. The pottery artifacts were essentially fragments of biscuit and finished products (Almeida et al. 2001).

Vila Nova did not have nearby white-clay sources. The white clay used was bought in Lisbon (Leão 1999) and possibly from Coimbra (Sebastian 2010).

The ceramic fabrics are very similar to Lisbon's: very homogenous and hard with some natural quartz and micaceous inclusions. Light buff fabrics are the most frequent although sometimes they have a pinkish tone, probably due to the use of some red clay.

The enamel is of a high quality with an elevated percentage of tin, very thick, white, and shiny. Blue decorations tend to be slightly darker than those from Lisbon and Coimbra, which may imply different ways of production or even variations in the kiln temperature. The use of yellow is not very frequent in Vila Nova productions. Although the decorations are a clear imitation of those produced in Lisbon and Coimbra, the decorative technique can be different from those centers: some vessels have a "relief" decoration.

World Distribution

Portuguese faience is regularly found across the world, especially in Atlantic coastal shores. This distribution cannot, however, have the same interpretation in all these places.

Portuguese colonies such as Brazil, Cape Verde, Goa, or even Madeira and the Azores were considered to be an extension of Portuguese territory. In this sense, the types of pottery found in such places are similar to those found in mainland Portugal ranging from high-quality vessels used by political and religious elites to lower-quality ones used in domestic contexts (Fig. 5).

This business was operated by Portuguese merchants as documented by port books. Pottery occupied just a small amount of space in the ships' cargo list. This was in fact a regular trade with several ships taking pottery around the year towards these colonies (e.g., Gomes et al. 2012).

Portuguese Faience and Historical Archaeology, Fig. 5 Portuguese faience plate found in Cape Verde. (Photo by T. Casimiro)

Although less frequent, the presence of Portuguese faience in Spanish colonies cannot be ignored. Portugal and Spain were united under one crown from 1580 until 1640, one of the most productive periods for Portuguese faience. The presence of such wares in places such as Florida, the Dominican Republic, and even Argentina and Uruguay is recurrent.

Considerable quantities of Portuguese faience have been found in England and in its colonies in the North Atlantic, such as Newfoundland, Massachusetts, and Maine, and further south in Virginia and Barbados (Pendery 1999; Straube 2001). At some sites it represents the second largest ceramic import after English wares (Pendery 1999). References to it as "Lisbon ware" can be found in probate inventories (Wilcoxen 1999).

English planters would like to maintain a similar lifestyle to what they had in their home country. In this sense they would import every commodity which allowed the maintenance of their social status, namely, furniture, textiles, pottery, and even food (Pendery 1999; Wilcoxen 1999). Faience was not an everyday export as one can see in England, Ireland, Spain, France, Denmark, Sweden, and Germany. An interesting exception is the pottery found in the Low

Countries where the presence of several merchants with Portuguese family backgrounds can in fact support such theory (Bartels 2003).

Future Directions

The occurrence of Portuguese faience in the world has to be considered in diverse perspectives. The evidence found in Portuguese colonies is easy to comprehend and interpret. Portuguese settlers took Portuguese faience with them continuing to use what were their daily ceramic commodities. Spanish colonies, bearing in mind their political proximity to Portugal during six decades, were also privileged in the knowledge and use of Portuguese wares, acquiring easily and transmitting the idea of European and Eastern merchandises.

As for English colonies, the presence of Portuguese faience is related to the ability to acquire a high-quality good, produced in Europe, that could help European settlers to maintain a European lifestyle.

Lisbon was the most preferable workshop and most archaeological samples found in overseas contexts were in fact produced there. Nevertheless, one cannot underestimate Coimbra and Vila Nova since many plates and bowls produced in these workshops were in fact recovered in places such as Ferryland in Newfoundland and Devon in England.

Even though these ceramics are present in large amounts in other countries, it is believed that these were just a complement of a larger trading system involving wine, sugar, and olive oil but where all sorts of products were traded from food stuff to clothes, furniture, and of course pottery, among many other things.

Archaeometric studies are required to provide information to determine the extent of trade and consumption of Portuguese faiences in Europe, Africa, Asia, and the Americas.

Portuguese Redwares and Coarse Wares in Historical Archaeology

Tânia Manuel Casimiro
Departamento de História Faculdade de Ciências Sociais e Humanas, Instituto de Arqueologia e Paleociências da Universidade Nova de Lisboa, Lisbon, Portugal

Introduction

Portuguese coarse wares (*cerâmica comum*) were the daily ceramic objects used in Portuguese households in medieval and postmedieval

Portuguese Redwares and Coarse Wares in Historical Archaeology, Fig. 1 Map of Portugal with the places mentioned in the text

times (thirteenth to nineteenth century). It is an unfortunate, nonspecific term that does not take into account regional production differences or the differences between the very fine, thin-walled cups and the rough cooking pots (Fig. 1).

Definition

The term refers to ceramic objects produced with brown, black, red, and orange fabrics tempered with quartz and micaceous inclusions. The types of surface treatment include simple smoothing with a wet cloth, burnishing, and coating with a clay slip. Although coarse wares appear in many different colors, redwares were the most common. All were wheel-thrown. Closed vessels show regular and deep potter's finger marks on their interior surface.

Key Issues/Current Debates/Future Directions/Examples

The Search for a Name: International Discussion

Portuguese coarse wares have been recovered in many countries and former colonies although, until recently, they were given other names by non-Portuguese archaeologists. The most famous designation was Merida-type ware, assigned by John Hurst in the 1960s thinking that this was, in fact, a Spanish product that maintained the Roman tradition of the *sigillatas* from the Merida region. Hurst recognized his error some years later (Hurst et al. 1986), but by then the name had already been adopted in English archaeological literature.

Portuguese ceramics were first identified outside Portugal in 1854 when in England reference was made to *cerâmica empedrada*, or stone inlaid pottery, from the Estremoz region (Hurst 2000: 24). For many years, it was considered to be made exclusively in High Alentejo, Estremoz, where there was an important postmedieval production center. However, it is now evident from the finds being made outside Portugal that they were not exclusively manufactured in that area. Production was certainly more widespread (see Martin 1979: 291).

Alexandra Gutierrez (2007) was the first to define the Merida-type ware as "Portuguese coarse ware" as a result of studying hundreds of shards found in a single site in Southampton, England. Gutierrez was unable to establish secure production centers, but today the vessel shapes presented in the study indicate Lisbon, Aveiro, and possibly Coimbra as three very likely production areas.

In 2008, Sarah Newstead also used the same designation when studying large amounts of Portuguese coarse wares found in Newfoundland, which were also made in different areas of Portugal.

However, other names have been given to these wares. Ian Baart (1992) published some Low Countries finds as *sigillata* from Estremoz, although in this designation he included not only burnished ceramics but also fairly common wares sometimes decorated with embedded small white quartz and feldspar stones (Fig. 2).

Examples of Portuguese coarse ware have been found in New World colonies where it is called feldspar-inlaid redware and orange micaceous ware (Deagan 1987: 40–41), although micaceous pottery was also native to the New World.

The variety of Portuguese productions was such that coarse wares once found outside Portugal were called by very different names. In this

Portuguese Redwares and Coarse Wares in Historical Archaeology, Fig. 2 Pot with small quartz-stone decoration found in Azenha de Santa Cruz, Torres Vedras by G. Cardoso and I. Luna. (A) 50 cm. (Photo by G. Cardoso)

sense, what has been designated so differently in English literature was mainly produced in Lisbon, Coimbra, Aveiro, Porto, Estremoz, Lagos, and possible other Algarve cities such as Silves.

Shapes and Function

Portuguese coarse wares appear in many shapes for daily household activities, for industrial processes, and for commercial activities.

Domestic vessel forms include cooking pots (*panelas, frigideiras, caçoilas*), often with their respective lids (*tampas, testos*); cups (*púcaros*); plates and bowls (*pratos, taças*); bottles and jars (*garrafas, jarros*); costrels (*cântaros, cantis*); large flared dishes (*alguidares*); funnels; chamber pots; and chafing dishes. For industrial use, there were sugar cones (*formas de açúcar*) and syrup pots. For commercial use, there were olive jars (*anforetas*).

Cooking pots used to boil, fry, or stew occur in various sizes that present globular or hemispherical shapes with convex bases, everted plain rims, and horizontal, vertical, or even triangular handles (Fig. 3). The countersunk lids with knob handles are frequent and easily recognizable finds.

Thin-walled cups (*púcaros*) with burnished exteriors, sometimes decorated with vertical lines, finger impressions, and appliqué are some of the most recognizable Portuguese coarse wear products (Fig. 4).

Bowls vary in shape: hemispherical, convex, or slightly carinated. They can have a concave, recessed base or a foot ring. On the exterior wall just below the plain everted rim, there may be a decoration of incised lines (Fig. 5).

Flared-rim plates, with the same types of bases as bowls, usually have a burnished interior.

Jars and bottles, used to store and serve liquids such as water, wine, and olive oil, have narrow flat bases and straight necks terminating in a multiplicity of rim forms.

Rilled, tall-neck, globular costrels served as water containers and are also frequent finds in archaeological excavations.

Large, flared bowls with everted or plain rims served a variety of functions from food preparation to laundry and dish washing. Their diameters range from 30 to 80 cm. Most are burnished but some examples present an interior yellow and green lead glaze. These might have been expensive items since evidence of repairs when broken is frequent.

Portuguese Redwares and Coarse Wares in Historical Archaeology, Fig. 3 Cooking pots found in Rua Homem de Cristo Filho, Aveiro. (After Barbosa et al. 2008: 127)

Funnels, with a wide round top and a narrow tube coming out at the bottom, were used for pouring liquids into containers. Though extremely functional, it is not a common artifact in Portuguese archaeological sites.

Chamber pots were fundamental objects in every fifteenth- and sixteenth-century house and are usually recovered in every domestic site, though their frequency increases in later chronologies. Characterized by their flat bases, tall

Portuguese Redwares and Coarse Wares in Historical Archaeology, Fig. 4 *Púcaros* and Chinese porcelain dishes found in Convento de Santana, Lisboa. (After Gomes and Gomes 2007: 85)

cylindrical bodies, everted rims, and usually large flat or concave handles, they can be found glazed or unglazed.

Chafing dishes were used in association with cooking pots to heat and cook food. Their sizes are as variable as those of cooking pots.

Sugar cones and syrup pots were used by the industry and are frequently found across Portugal but especially in the areas around Lisbon and Aveiro where these were produced for local consumption and to the cclones for export.

International literature has often classified olive jars as exclusively Spanish products. Nevertheless, nowadays it has been established that these were made in other countries such as Portugal and some New World settlements. Although earlier vessels usually presented a flat bottom, a narrow neck, and two small handles, from the mid-sixteenth century onward, the shape is rather similar to Spanish olive jars, but the paste is definitely Portuguese.

Although diverse shapes are known, Portuguese workshops tended to produce similar objects, and one can find straight similarities between Algarve, Lisbon, or Aveiro productions and sometimes for long periods of time.

Production Centers

Coarse wares were made in almost every city in Portugal. Kilns are not frequent finds in archaeological excavations, and only about half-dozen have been identified in postmedieval contexts. Nevertheless, large ceramic assemblages have been found in major cities, which in some cases, especially where written evidence (such as charters, wills, and price lists) is available, almost certainly point to the existence of potters and production sites (Fernandes 1999).

In 1980, a rectangular kiln, dating from the mid-sixteenth century, was found in Mata da Machada (Barreiro). Although many types of pottery were found at the site, from coarse wares to lead- and tin-glazed ceramics, the coarse-ware evidence indicates the production of sugar cones, and several domestic shapes such as cooking pots, cups, plates, bottles, and others, and also small vessels decorated with inlaid quartz stones, a decorative style thought for many years to be exclusive to the Estremoz area.

News of kiln sites in Lisbon is not rare but no evidence of a postmedieval kiln has been published. Nevertheless, Lisbon must have been one of the largest production centers in Portugal, producing for local consumption and for export. In 1552, for example, there were about 60 kilns producing redwares (*louça vermelha*), mostly in the medieval potter's quarter (Casimiro 2011b) (Fig. 6).

No kiln has been found in Estremoz. Nevertheless, ceramic products from that area were

famous in the early modern era among rich and poor, and written evidence confirms this. In the 1610 book *Descrição de Portugal*, Duarte Nunes de Leão mentions that fine and thin Estremoz cups were appreciated across the entire kingdom. This author also refers to similar products in Lisbon, Pombal, and Montemor-o-Novo. In this last site, there was a special type of production. The fabric was full of very small, white, quartz stones. Examples have been identified in Amsterdam and London. Once, during a dinner, King Sebastião drank from an Estremoz cup, while all the guests used silver and gold vessels, claiming that he enjoyed its "earthen" taste, and several members of the Iberian royal family appreciated these cups (Vasconcellos 1921: 32). Moreover, in 1687 two ships set sail from Lisbon to England, and among the diverse cargo there were two boxes of Estremoz pottery (Casimiro 2011a: 181). The Estremoz' kilns produced mostly cups, bottles, jars, and bowls with burnished surfaces and stamped or small, white, inlaid quartz-stone decorations.

Portuguese Redwares and Coarse Wares in Historical Archaeology, Fig. 5 Bowls found in Rua Homem de Christo Filho, Aveiro. (After Barbosa et al. 2008: 124)

One of the most important northern production centers was Aveiro. No kiln has been found there, but several terrestrial and underwater archaeological excavations have revealed a rich production area. The coarse-ware vessels present orange micaceous fabrics and often burnished decoration with vertical lines. One of the most important excavations is that of the shipwreck Aveiro A, where an immense pottery cargo was recovered giving an idea of the type of shapes produced and their similarity to many finds made inside the city walls (Alves et al. 1995; Bettencourt and Carvalho 2008; Barbosa et al. 2008).

Many other towns in Portugal produced pottery, for example, Coimbra, Palmela, Porto, and Lagos.

Portuguese Redwares and Coarse Wares in Historical Archaeology, Fig. 6 *Púcaros* with modeled decoration found in Convento de Santana, Lisboa. (After Gomes and Gomes 2007: 85)

P

One specific type of Portuguese coarse ware is the so-called black pottery (*cerâmica negra*), traditionally made in the northern part of the country in centers such as Tondela or Bisalhães, among others. It does not seem to have had an important international distribution. Only two vessels are known abroad, in London and Amsterdam, two cities that had commercial relations with Portugal.

A kiln found in Silves (Algarve) in 2002 revealed the production of thin-walled cups, believed for many years to be exclusive to production sites in the center of the country, and other less-fine vessels (Gomes 2008) that tend to give insight into the difference between kitchenware and tableware.

World Distribution

Portuguese coarse wares, with a variety of shapes and decorations, from simple vessels to richly decorated ones, have been found in many countries around the world: England, Ireland, Scotland, the Low Countries, Denmark, Iceland, Germany, Canada, the USA, Brazil, and several African locations (e.g., Hurst et al. 1986; Baart 1992; Orser 2002; Gutierrez 2007).

It is believed that these vessels reached their destinations with two purposes: as household wares and as shipping containers for Portuguese produce. Portuguese ship registers reveal the export of many types of household coarse ware pottery, as can been seen in the lists of goods leaving Porto and sailing to England, Newfoundland, New England, Brazil, and Africa, carrying Estremoz, Aveiro, and even Northern pottery (Barbosa et al. 2008: 134).

The evidence of containers for the shipment of Portuguese commodities such as olive oil, olives, sweets, marmalade, and other items can also be seen in ship registers (Casimiro 2011a: 184).

It is not easy to infer from these documents the major production center for exported Portuguese ceramics, but the archaeological evidence outside the country suggests Lisbon, Coimbra, Aveiro, and Estremoz as four of the major production areas.

Portuguese coarse wares due to their color, micaceous aspect, shape, and decoration are a recognizable product in European, African, and New World settlements. This is confirmed, in part, in paintings by Portuguese and European artists such as Josefa de Óbidos, Velasquez, Frans Francken, among many others, in which Portuguese coarse wares appear (Vasconcellos 1921: 13).

It was on everyone's table in Portugal, used by rich and poor, as shown by written evidence. It was available in foreign countries and far away colonies as indicated by the archaeological evidence.

Portuguese Tiles (Sixteenth to Eighteenth Century)

Tânia Manuel Casimiro[1] and Mariana Almeida[2]

Introduction

One of Portugal's most impressive ceramic productions was tiles. Although floor tile production is known in medieval times, wall tiles were only manufactured since the mid-sixteenth

century. These are square ceramic plaques – although other shapes are known – the majority of times produced with light buff fabrics, covered with glazes and creating patterns or a scene with the objective of covering walls. From geometric motifs, which are combined to create patterns, to figurative tiles telling stories, this is one of the most important architectonic features in early modern Portugal. The earliest known production site in Portugal is in south bank of the River Tagus in Santo António da Charneca, producing in the mid-sixteenth century. At the same time, Lisbon was also producing tiles. By the early seventeenth century, the production was already spread to other parts of the country, namely, Coimbra and Vila Nova (Porto). Although tiles are a wide generalized production, they were used essentially in the decoration of the inner walls of churches, convents, and palaces and occasionally fountains and gardens.

No floor tile production kiln or workshop is known in Portugal so far. However, a research project about medieval floor tiles with archaeometric analysis concluded that the tiles in Alcobaça were in fact produced in Portugal (Trindade 2018). These followed the style of the Cistercian tile, a European tendency developed during the life of Bernard Clairavaus (Cothren 1982). In Alcobaça, in the second half of the thirteenth century, there are white and turquoise blue floor tiles as well as incised decorations (Trindade 1998). This is the period when other church and palace floors are also covered with similar tiles such as the ones found in the National Palace of Sintra (King Dinis palace), the chapel of Estevão Domingues and his wife (1305) in Lisbon cathedral, as well as the King João I palace in Coimbra dated from the late thirteenth century (Trindade 2007). In the National Palace of Sintra, the floor of a room built in the late fourteenth century (where later in the seventeenth century King Afonso VI is going to be imprisoned) reveals a different pattern and probably already a transition to a *mudejar* taste (Silva 1995). The late fourteenth century is the moment when floor tiles start to be used in walls (Trindade 2007), something that continued in the fifteenth century. It is quite likely that tile makers existed in Lisbon during the middle ages; however, it is only in the late fifteenth century that documents attest the presence of a tile maker with a Moorish name *Alle Azuleiro*, possibly producing similar objects to the ones imported from southern Spain (Trindade 2007).

Arista, Cuerda Seca, and Historiated Tiles (Sixteenth Century)

Medieval thirteenth- and fourteenth-century buildings had impressive tile floors; however, during the late fifteenth and sixteenth century, a general taste of covering the walls of important buildings with tiles develops in Portugal, mostly inspired by Islamic traditions still surviving in southern Iberia. The majority of the tiles used in Portugal in the early sixteenth century seem to have been made in Seville, and at least three surviving documents support their origin. The tiles found in Portugal and made in southern Spain correspond essentially to *alicatados*, *enxaquetados*, cuerda seca, and arista tiles.

This fourth technique, supposedly invented by Niculoso Pisano, an Italian potter settled in Seville (Pleguezuelo Hernandez 2007) is going to be rather successful allowing for a huge increase in production. If in the cuerda seca tiles a mixture of grease and manganese was used as an outline of drawings to separate colors, in the arista case, wooden molds with carved drawings would be used as molds to produce hundreds of similar tiles. The reliefs impressed in the clay would avoid that different glazes mixed. These were painted with lead or tin glazes. Their production technique developed a standardized product with the manufacture of thousands of similar objects (Pleguezuelo Hernandez 2007, 365).

The import of such tiles was so frequent that this could have been the reason which made Portuguese potters start to produce tiles using the similar techniques.

It is difficult to define when was this tile production made for the first time in Portugal; however, the oldest archaeological evidence was found in a mid-sixteenth-century workshop found

in Santo António da Charneca, in the south bank of the River Tagus.

The excavation discovered a kiln and some wasters where the tiles, in biscuit and already glazed were found (Cardoso et al. 1997). This was in fact a big novelty since these types of tiles, although some researchers already suspected a Portuguese production (Trindade 2007), had no hard evidence and the majority of tiles were suspected to have been made in Seville and imported into Portugal.

This production is not only confirmed by the archaeological record but also by archaeometric analysis (Fig. 1) (Ferreira et al. 2014). The tiles found in this excavation are decorated with floral and geometric patterns and glazed painted with white, green, brown, and yellow, creating patterns. As for the cuerda seca, although no tiles were ever found associated to production sites, once again archaeometric analysis made in tiles found in the Monastery of Santa Clara-a-Velha, in Coimbra, and their technical differences when compared with Seville and Toledo products suggest that these were also made in Portugal (Coentro et al. 2014). The investigation concerning this Portuguese production is still scarce, and most of the tiles found in archaeological contexts are still usually characterized as Spanish although that assumption might need some revision in the near future (Fig. 1).

Portuguese Tiles (Sixteenth to Eighteenth Century), Fig. 1 Arista tiles manufactured in Santo António da Charneca (after Trindade 2008, 160)

In spite of this evidence, arista and cuerda seca tiles were seldom produced, and in fact, the majority of tiles continued to be imported until the late sixteenth century.

There is still no evidence that *enxaquetados* were produced in Portugal although the pastes from the tiles found in Lisbon seem quite similar to Lisbon pottery productions and their amount in archaeological excavations suggests this production. This technique corresponds to the use of very small tiles, glazed with different colors which are combined in order to form geometric patterns. Their use in Portugal is frequent since the late fifteenth century, especially in churches and palaces. As for *alicatados*, very small tiles shaped as stars and diamonds, used to form compositions, they are so rare that it is almost impossible to have been produced in Portugal (Casimiro and Sequeira 2018).

This type of tiles known as *hispano-mourisco* or *mudejar* is going to get direct influences from the still surviving influences of centuries of Islamic presence in southern Iberia with geometric and phytomorphic motifs creating geometric symmetries. Many buildings in Portugal had their walls covered with these tiles. Some of the most outstanding examples can be found in the National Palace of Sintra. Originally built in medieval times, this building is going to be highly refurbished in the early sixteenth century and a large portion of its inner rooms decorated with cuerda seca and arista tiles. These have many different decorations ranging from the traditional floral and geometric pattern combined in large compositions to tiles with the arms of King Manuel, a royal demand to decorate the palace. One of the largest archaeological collections of *hispano-mourisco* tiles ever found was also associated to a palace, owned by the Penafiel Counts in Lisbon, where hundreds of these tiles were found and believed to form the decoration of the first floor (Bargão et al. 2017). Although the authors sustain, based on style, that these tiles were all imported from Seville, this attribution cannot be certain without further work. Many other places are known in the Lisbon area or up the Tagus River although only occasionally published (Casimiro and Sequeira 2018).

Churches and monasteries were also large consumers of these arista tiles. In Portugal, some of the most iconic religious buildings, as tiles are concerned, are located in Coimbra, where the cathedral still conserves part of its walls covered with this decorative solution, mostly likely of Seville production based on a large quantity of tiles bought from that Spanish city in 1503 (Goulão 1986), although a large portion of the tiles in this building were removed in the twentieth century.

This type of tiles was in fact the most recurrent in Portugal, although certainly not the only production. Following the Italian, Flemish, and Spanish style, some tile producers are going to paint *historiados*. This type of polychromous panels uses colors such as green, yellow, brown, and blue on a white background to actually tell a story, most of the times inspired by classic mythology or biblical tales. The technique is the same as tin glaze production which paints a colorful scene over a white tin glaze layer. It is said it was Niculoso Pisano who introduced this technique in the Iberian Peninsula.

Some of the most well-known examples are conserved in Quinta da Bacalhoa, a large estate owned in the sixteenth century by Brás de Albuquerque, an important figure of Portuguese nobility and an admirer of Renaissance style and architecture. The most famous panels are a representation of Susanna and the Elders and Abduction of Europa (Fig. 2), possibly made by a Flemish tile maker who settled in Seville named Frans Andries (Pais et al. 2015). However, other examples are known in the Lisbon area such as a panel in one of the São Roque church chapels or the Senhora da Vida panel, today kept at the Lisbon tile museum yet made for the Santo André Church around 1580 (Morais 2012). These tiles were clearly being made in Lisbon, and two of the most distinguishable craftsmen were Marçal de Matos and Francisco de Matos, probably relatives, who must have been active somewhere between 1560 and 1590 and actually signed and dated a few of their panels (Fig. 2). Some other tile craftsmen are known such as the Flemish João de Gois and Filipe de Gois, possibly relatives. Until recently they were only known from written

Portuguese Tiles (Sixteenth to Eighteenth Century), Fig. 2 *Historiado* tiles with the biblical tale of Susanna and the Elders from Quinta da Bacalhoa

documents; however, a few years ago, a panel in Graça Gurch has a signature recognized as the initials of João de Gois (Pais et al. 2015) revealing how multicultural tile production was in Lisbon in the late sixteenth century.

The style of these tiles can in fact be followed all the way into Italy where ceramic artists were painting such scenes in walls and smaller objects such as ceramic vessels.

Pattern Tiles (Seventeenth Century)

If the sixteenth century combines different styles and decorations, the seventeenth century is going to be dominated by pattern tiles, sometimes also called repetition or "carpet tiles." These are replication tiles permeated by decorative influences from the Arabic, Flemish, and Far Eastern traditions, which were meant to cover a large surface in a relatively cheap and easy way. They follow the tradition of the *hispano-mourisco* tiles from the previous centuries, with its symmetry, geometry, and rhythm.

If only one production center is securely known for earlier periods, from the early seventeenth century onward, there are three production centers, namely, Lisbon, Coimbra, and Vila Nova de Gaia. These are the same centers which produced tin-glazed wares (Portuguese faience), since these two productions shared similar techniques and, thus, were fired in the same kilns and possibly made in the same workshops. In Coimbra, this production is still not archaeologically attested, although tin-glazed wares are documented there since 1603 and in Vila Nova de Gaia since 1605 (Gomes et al. 2013).

There are some differences between tiles from these three locations, allowing a more or less accurate macroscopic distinction. Lisbon tiles are slightly larger, measuring 14 cm on each side, while the others show 13 or 13.5 cm. On the other hand, the colors are darker in Vila Nova de Gaia (particularly the yellow tones, which are more brown than golden, as some yellows are meant to represent gold or other metals (Pais 2012b) and Coimbra; only Lisbon uses green and manganese purple. Given that both tiles and faience were produced with the same "recipes" for glazes and fabrics, the glaze from Coimbra has a rougher appearance and a yellowish tone (Meco 1989) (Figs. 3 and 4).

Portuguese Tiles (Sixteenth to Eighteenth Century), Fig. 3 Pattern tiles. Campo de Santana Convent, Lisbon (after Almeida et al. 2018, 264)

Portuguese Tiles (Sixteenth to Eighteenth Century), Fig. 4 Pattern tiles. Campo de Santana Convent, Lisbon (after Almeida et al. 2018, 264)

There are different types of patterns, depending on how many tiles it takes to create the repetition element 2 × 2/1, 2 × 2/2, 4 × 4/2, 4 × 4/4, 6 × 6, and 12 × 12. The simplest patterns (2 × 2) are obtained through the rotation of one tile. The decoration of the tiles is as if unfinished and contains continuity elements, creating a design through the continuous interconnection of ornaments. By adding tiles, the pattern can be extended infinitely, adapting to the size of each wall (Meco 1989; Simões 1997).

The larger patterns were meant to occupy wider areas. The most frequent ones are the smaller patters of 2 × 2, which are also the most numerous; the larger patterns have a smaller variation of designs, but their simplicity makes them quite common. The largest pattern conceived by the Lisbon workshops displays 12 tiles on each side, so with 144 tiles per module, called "Marvila" pattern (Meco 1989; Simões 1997; Pais 2012a).

Patterns are always limited by tile frames which follow the same rules. There are three types – *Friso* (frieze), *Cercadura* (frame), and *Barra* (bar) – with half, one, and two tiles in height, respectively. These could be used alone or together, often following an arrangement with all three, from smaller to larger. To obtain a *friso*, a normal-sized tile is produced, with two similar designs subsequently cut in half. *Cercaduras*, with one tile in height, have two clear horizontal edges, often dissimilar, to limit the decoration. *Barras* also present edges, and by having two tiles in height, they present an internal horizontal axis where the upper tile mirrors the other. These last two types both present corner and countercorner elements (Simões 1997).

The colors used are mainly blue, yellow, and white, with some details in green and orange until the third quarter of the seventeenth century and only in blue and white until the end of the use of patterns, something which occurs in the first decade of the eighteenth century. Purple was introduced in the second half of 1600s and was mainly used on figurative compositions.

As for decorations, we can generically group them into four different periods. The first ones appear still in the last decade of the sixteenth century and go on until around 1630, they follow the older "*caixilho*" simpler monochrome geometrical compositions and add polychromous tiles in the places once occupied by white elements, and these did not permit lateral decoration connections, with only one tile or four tiles with only one rotation axis. The most famous pattern of this period is called "*ponta de diamante*" (diamond heads), where the lateral designs are intricate geometrical designs which frame the central motif.

A second period, from around 1630 to 1650, sees a proliferation of patterns, with influences from the Sevillian tiles, Italian and Flemish decorations, and Far Eastern textiles and tapestries. This period, which roughly corresponds to the last decade of the Iberian Union and the first one of the Restauration, is marked by a difficult economic juncture which partially explains the popularity and spread of pattern tiles, since they are cheaper and easier to apply. It is also the period when the cobalt used to create the color blue is more diluted since it was very expensive (Pais 2012a). Patterns can be grouped into "families" where a recurrent central popular theme is altered but maintains an element of recognition, the most popular ones being corncobs, camellias/roses, vine/acanthus leaves, palmettes, and ropes/lacework. Each had multiple variations though the first two were especially proliferous.

A third period, from approximately 1650 to 1680, which roughly comprises the reign of King Afonso VI, is marked by the definite end of the war and the beginning of an economic recovery, as well as the rise of a new nobility which felt the need to assert their power and influence. This period is characterized by more intricate new designs, with less occurrences, sometimes only made for specific orders, which coexist alongside the older designs with new variations. The color orange disappears, and the manganese purple arises, along with a tendency toward a whiter background. Flower elements emerge in the wake of other emergent decorative styles: single figure and altar fronts.

The fourth and last period of pattern tiles took place from 1680 to 1700, approximately the reign of King Pedro II, when the peace with Spain was

completely set. The economic environment and the newly established nobility were favorable to the consumption of foreign luxury goods, such as Dutch tiles and Chinese porcelains, with their aesthetic that deeply influenced the Portuguese ceramic production. Pattern tiles were reduced to a blue and white palette, although with the same designs and a dominance of the larger patterns of 4 × 4 and 6 × 6 (Monteiro 2007; Pais 2012a).

Small panels with religious symbols complement the pattern tiles in churches, being particularly common from 1645 to 1670 and usually presenting an inscription with the name of the donor and a religious quotation. One of the most usual compositions shows a central monstrance surrounded by two praying angels, often holding thuribles. Other symbols are also usual, such as the emblems of religious orders or allegories.

There are also panels depicting saints, the most common of which are the Virgin Mary, John the Baptist, the Holy Family, and Saint Anthony. Other less popular saints were also painted (Almeida et al. 2018).

Also found in churches decorated with pattern tiles are altar fronts (Fig. 5). As the name suggests, these were meant to cover the part of the altars which faces the congregation and replaced the rich and intricate textile altar cloths, although heavily influenced by and often copying them, as clearly indicated by the golden painted fringes on the edges of the compositions, and mingling the decorative influences of Far Eastern models with catholic imagery. As for chronology, these compositions were created from approximately 1650 to 1680.

The iconography of these panels comprises a strip of land on the bottom with animals (deer, gazelles, lions, etc.) and vegetation (palm trees, rose bushes, and various undefined others) which branch out into an upper level representing the sky or paradise, filled with fruits, flowers, and birds (eagles, peacocks, swallows, and diverse birds of paradise). Sometimes the center presents emblems from religious orders or coats of arms (Meco 1989; Curvelo 2012a).

As for nonreligious tile panels from the seventeenth century, they were less numerous, and the ones who still survive came from the noble houses around Lisbon. These panels are polychromous and fall mainly into three categories: nature, mythology/allegories, and social representation. The first, much like the decoration of altar fronts, presents vegetation and wild animals inspired by Far Eastern textiles, as well as animals from

Portuguese Tiles (Sixteenth to Eighteenth Century), Fig. 5 Altar front panel, Quinta do Bairro, Vila Nova de Famalicão

P

the America (mainly exuberant birds) and Africa (such as camels or leopards).

The second theme comprises mythological depictions, which will continue to exist throughout the centuries. Classical gods, muses, and other characters are featured, and most of these compositions were based on engravings by foreign authors, mainly Italians at this stage. As for allegories, we find depiction of the zodiac signs, months, seasons, or continents. There was also what is usually called *macacaria* or *singerie*, which has a clear satirical nature and places animals in human costumes and situations with a moral undertone, much like with fables. The most famous of these compositions is called "the chicken marriage," now in the National Tile Museum, where a chicken is transported in a carriage with a parade of music-playing monkeys. Indeed, the monkeys are constant feature of this genre, and it is where it takes its name from, since monkey = macaco (pt.) = singe (fr.).

The third category comprises scenes that range from everyday life and/or court compositions, such as hunting or dinning, to battles of the Portuguese Restoration War. The best example of tile panels in civil architecture with nonreligious themes comes from the marquises of Fronteira Palace in Lisbon, where the estate and gardens are profusely decorated with tiles depicting the family's lineage, detailed accounts of the battles of the Restoration War, as well as gallant and hunting scenes. Portuguese and Dutch tiles stand side by side in this palace, in a display of wealth and status for a noble family who rose to power in the wake of that conflict.

One very popular design, inspired by Flemish compositions, called *Albarrada*, comprises a large decorated vase filled with flowers surrounded by birds (the most common are parrots or peacocks) (Fig. 6). The first examples, dated from the late seventeenth century, are larger than their eighteenth-century counterparts and started out as colorful, following the overall chromatic tendencies. The designs became more stereotyped, smaller and repeated horizontally, occasionally with angels holding the vases, now sometimes baskets, and the birds might become dolphins or dragons. The use of *Albarradas* almost disappears in the Rococo period, with sporadic appearances with a much simpler design after 1755 which can be found until the nineteenth century (Meco 1989).

The seventeenth century also marked the expansion of Portuguese tiles throughout the world, even though there were already late sixteenth-century Portuguese arista tiles and geometric compositions in the Atlantic islands of Azores, Madeira, and Cape Verde (Meco 1998;

Portuguese Tiles (Sixteenth to Eighteenth Century), Fig. 6 Albarrada. Campo de Santana Convent, Lisbon (after Gomes and Casimiro 2007, 28)

Evans et al. 2017). The tiles were taken to the Portuguese territories of Africa and America, with smaller sets in places such as Cape Verde (Almeida 2018a), the city of Goa in India (Curvelo 2012b), and Macao (Meco 1998).

Brazil holds an impressive amount of Portuguese tiles, second only to Portugal itself, with more than 136 sets for the seventeenth and eighteenth centuries (Simões 1965). For that reason, Brazil deserves a special mention due to the high number of cases. There are no pattern tiles prior to 1630–1640, the penetration of which began in the northern states like Bahia. The Rio de Janeiro region began using them around 1660 onward, while the southern states and the São Paulo area only received tiles from 1680 to 1690, reflecting the settlement and type of occupation of the Brazilian territory. There were no special patterns created specifically for the Brazilian market, nor did all of the ones used in Portugal were used, the polychromous compositions are scarce and so are altar fronts (Simões 1965). Even though there was not a special production being manufactured only for this colony, there certainly was a Brazilian taste, explaining the presence, absence, and preference of certain motifs and types of tiles (Senos 2012).

As also happens with pattern tiles, the other seventeenth-century compositions were polychromous and became blue on white around 1670, although maintaining for the most part a manganese purple outline until 1680–1690. Around that time, other changes occur; the blue pigment began being diluted, creating gradients in order to suggest depth; and the contour becomes thinner and also blue (Meco 1989).

The Cycle of Masters (Eighteenth Century)

One of the first productions entirely with one color is called single figure (Fig. 7). These were directly inspired by Dutch single-figure tiles, although without their minutia and detail, since they were considered a lesser job and performed mostly by apprentices. The Portuguese production began in the third quarter of the seventeenth century and had a round edge to the central motif, afterward that is lost, and by the beginning of the eighteenth century, they gain their characteristic corner element, a stylized and simplified flower. Single-figure tiles show only one design at the center, with wide brushstrokes. The decorations are stylized, fairly simple, and highly repetitive, falling into some main themes: animals (birds and mammals), flowers and fruits, boats and buildings, landscapes, angels, humans, and sarcastic images (such as large-breasted women or drunken monks) (Simões 2010; Castro and Sebastian 2003). Although this type of tiles was also used in churches, as the case of São João de Tarouca where many single-figure tiles were retrieved from the archaeological intervention (Castro and Sebastian 2003), they were mainly used in kitchens and infirmaries prior to the 1755 earthquake and afterward were placed in secondary spaces such as corridors or passages (Meco 1989).

Portuguese Tiles (Sixteenth to Eighteenth Century), Fig. 7 Single-figure tiles Quinta de Santo António (Vila Franca de Xira, Portugal)

In the last decade of the seventeenth century, Gabriel del Barco (1648–1703?) began its career as a tile painter after years as ceiling painter and would became a reference in a transition period which would pave the way to the "the cycle of the masters." His works were much larger than previously, with a progressive complexity of the

compositions but keeping the relatively straightforward one or two tile frames (Meco 1989).

Soon after other names joined him, with a scholarly artistic formation, able to compete with Dutch tiles and thus fulfilling a market failure. The most famous were Manuel dos Santos (active between 1702 and 1730), António de Oliveira Bernardes (1660?–1732), and the unnamed painter known as P.M.P. (active between 1717 and 1730). They brought the baroque aesthetic to the compositions, with large scenic depictions, expressive actions and characters; they also overcame the previous problems of scale and perspective in order to create optical illusions and *trompe-l'œil*, which did not exist before.

All of the masters produced large figurative panels, with interconnected scenes in order to create a coherent narrative (Figs. 8 and 9). The commissions were mainly for religious environments, and, therefore, with religious themes, the exception comes from P.M.P., the one with the largest secular body of work in palaces and noble houses throughout the Lisbon area.

The most famous panel of this period is the panel known as the "Great Panorama of Lisbon," with 1376 tiles in total, which belonged to the Palace of the Counts of Tentúgal, Lisbon, and is now a part of the Museu Nacional do Azulejo collection. It was probably painted by Gabriel del Barco, albeit with contributions from other painters, around 1698–1699. This view of the city from the river, as if the observer is partaking on a cruise downstream, is quite rigorous in the depiction of the main buildings and water front but somewhat more stylized in the urban neighborhoods. It spans almost 14 km, from the Jamor Valley in the west to Xabregas on the east side (Meco 1985; Flor et al. 2014).

The work of these painters was very individualized, sometimes enabling an identification when not signed, which at this point was rare, unlike the seventeenth century where all production is anonymous.

This period lasted until approximately 1725, paving the way to the next generation of tile painters collectively known as the "Great Joanine Production" which lasted roughly until 1755 and is named after King John V (r. 1706–1750).

This period is marked by the incoming flow of gold and gemstones from Brazil, first discovered in 1697, and the increase of grandeur and sumptuous lifestyle of the king and court. Lavish new buildings were being constructed, decorated with a combination of tiles and gilded woodcarving.

Portuguese Tiles (Sixteenth to Eighteenth Century), Fig. 8 São Vicente de Fora Monastery, Lisbon

Portuguese Tiles (Sixteenth to Eighteenth Century), Fig. 9 São Lourenço Church, Almancil

The demand for tiles created a production of serial figurative compositions, most of them based on French or Dutch engravings, putting an end to the previous individualism. The important features of this period's taste were the theatricality and the amount of decoration on each panel. The backgrounds and landscapes also receive a great deal of detail, with the correct representation of shading and proportions of trees, fountains, or buildings. The cobalt blue is now watered down to create multiple shades, and multiple brushstrokes are overlapped to achieve a deeper tone, creating a dynamic effect.

The frames of figurative compositions suffered an evolution in the 1730s, with the inclusion of baroque motifs and style, with seraphs in tunics, the illusions of architecture and stage settings given by valances, fringes, flying cherubs, and pilasters, greatly influenced by the Italian opera.

Despite the standardization characteristic of this period, particularly in its beginning, which leads one author to call it the "period of the anonymous workshops" (Simões 2010), some painters are known for their individual work, since they kept signing their compositions. The most prolific and famous were Teotónio dos Santos (1688–?), Valentim de Almeida (1692–1779), Policarpo de Oliveira Bernardes (1695–1778, son of the previously mentioned António de Oliveira Bernardes), and Nicolau de Freitas (1703–1765).

The best examples from this period can be found in the Convent of São Vicente de Fora, Lisbon; the Colégio do Espírito Santo, Évora (formerly a Jesuit seminary and now the University of Évora); or the cloisters of the Porto Cathedral.

The themes displayed are vast and therefore hard to catalogue. They range from religious depictions of the lives of saints, Jesus, and the Virgin Mary, scenes from the Old Testament, classical mythology, and more worldly themes such as landscapes, banquets, parties, hunting, and leisure scenes, placed on the palaces of the nobility. Most panels were painted after published foreign engravings, spanning all mentioned themes (Simões 2010).

This period also sees the beginning of a typically Portuguese type of tiles called invitation figures, which spanned chronologically until the nineteenth century. These are full-scale cut around

compositions showing male human characters that were placed at the entrance of great halls or meeting rooms, so that they were not seen from the outside. The first invitation figures were made by master P.M.P and were placed outside the chapter house of the University of Évora and until the reign of João V were restricted to the palaces of the top nobility and clergy. The characters depicted were firstly doormen or servants dressed in livery and halberdiers guarding the rooms, all portrayed with expressions and actions indicating an invitation to come in, reflecting the baroque ceremonials and theatricality, both religious and profane. After that period, invitation figures spread to the houses of the rich bourgeoisie and a second order of nobility. These have a more elaborate composition, frequently with a *trompe l'oeil* or an optical illusion, found in other spaces like staircases and hallways. Other characters are introduced at this stage, such as equipped soldiers, women, Turkish soldiers, and gentlemen, and musicians were hosted later on the nineteenth century. Invitation figures followed the tile aesthetic of each period (Arruda 1993, 2014).

A new introduction of color, with the emergence of the Rococo aesthetic, takes place around 1745 and becomes more widespread from the 1755 earthquake onward, coexisting with blue and white compositions for the next few decades. Yellow was the first color to be reintroduced, with notes in the compositions to create the illusion of gold, metal, or the sun, and the others followed suit. Manganese, since it can be diluted in water, started being used to create multiple shades of purple and the main part of the composition. It should be noted that the use of polychromy was restricted to the edges and ornaments which surround the main arrangement, frequently these continued to present *trompe-l'oeil* illusions to resemble stone architectural elements as well as metal decorations. The center continued to be painted only with one color, blue or purple, creating a contrast between them (Meco 1989).

After the earthquake of 1755, the demand for construction materials signified an increase of tile production, as the new houses were rebuilt and refurbished. A new period started with that natural event that lasted until approximately 1780, usually called *Pombalino*, after the Marquis of Pombal (1699–1782), minister to King Joseph I (r. 1750–1777) and the main actor of the reconstruction of Lisbon. The Rococo tendencies continued, with the polychromy on the edges and blue or purple in the central composition, side by side with blue only panels. New decorative elements and techniques were introduced at this stage; shell-like- and bat-wing-like decorations lined the edges of the compositions which are now somewhat asymmetric. As for techniques, sponges soaked with paint and applied over the tile were used, either to create the effect of clouds or tree tops or covering the entire tile and used as fringes to fill gaps between the tiles and other elements, another new effect was introduced, with large erratic brushstrokes in one or two colors, creating a marbled look (Meco 1989).

The themes displayed in figurative tiles remained roughly the same, with two distinct spheres: religious depictions of the Old and New Testaments and profane tiles with serial subject matters such as the four seasons, the elements, the months, or the star signs, as well as scenes presenting hunting, social gatherings and intimacy, dancing and music playing, and landscapes (Simões 2010; Câmara 2005). The new introduction is the compositions called chinoiserie, popular on the second half of the eighteenth century, so-called because they used Far Eastern and Chinese motifs such as landscapes and Asian daily life scenes, which fulfilled a European curiosity with the exotic east, mostly fueled by engravings published by Jesuit priests (Câmara 2005; Correia 2013).

A religious type of tile called *registos*, which already existed approximately since the 1740s in low numbers but gained a new dimension as a consequence of the climate of fear and religious fervor experienced in the wake of the 1755 earthquake, can be seen in the most affected cities like Lisbon, Setúbal, or Santarém and continued until the definite establishment of liberalism. These reflect a popular devotion to saints' protectors of the house and family, as well as those who offer protection against forces of nature. These can be divided into two categories: family protector

saints – the Virgin Mary, the Holy Family, and Saint Anthony (1195–1231) – and the saints that protect against natural disasters, Saint Martial (third century) and Saint Francis Borgia (1510–1572). Although we can make this distinction of intentions, these elements can be combined in the same registo. The *registos* are usually placed on the façade, over the door or windows after the reconstruction. Non-habitable structures such as mills, fountains, bridges, and cemeteries were also covered with protection. Usually these panels are indented, varying in size, with compositions of a single saint or two and more, sometimes one of them being put in a prominent place. Many times a votive inscription or a date is painted (Almeida 2018a).

Another type of *registo*, a more naïve arrangement, is the *Alminhas*, which can complement bigger compositions like the basis of a cross of large dimensions. These can be composed of several tiles, but the majority are single tiles. These are more modest demonstrations of faith and devotion, since most are of one or four tiles only. The number of souls in these representations may vary but is usually two – a man and a woman. They are placed in the center of the composition, emerging from the flames of Purgatory (Simões 2010) with their hands raised in worship. Only painted in blue, with a highlight of orange/yellow in the flames, these compositions usually have no frame or it consists on a straight simple line and occupies the entire area of the tile. The great majority of *alminhas* have a caption, usually only the initials to save space: PNAM – *Padre Nosso Ave Maria*, PA – *Pelas Almas*, and OPN – *Ora Pro Nobis* (Almeida 2018b).

Pattern tiles made a comeback in the late 1740s, slowly at first and only in the Lisbon region, gaining a more widespread use after 1755 since there was a huge demand for tiles at that point. These new patterns follow the same logic of lateral connections and rotation axes as their seventeenth-century counterparts, but they are slender in design, with a pronounced white background, combining small flowers and other phytomorphs with geometric elements, and they have a suggestion of shading given by darker tones to the colors in use and a diagonal flow to the overall scheme. The colors used were blue and purple at first, but polychromy was afterward the staple, and the frames used with them are frequently a variation of the main theme and follow the same color scheme.

These patterns were an early manifestation of the neoclassical taste and thus continued to be used throughout the eighteenth and into the nineteenth century (Correia and Silva 2004).

The 1770s see yet another change in taste and tile decoration, with the neoclassical style, which would last until the first decades of the nineteenth century. The new period marked the definite end of the blue only tradition and the complete establishment of polychromy, although the central composition of figurative tile panels remained only in blue or purple.

Neoclassical tiles were heavily influenced by the Louis XVI style and the discovery of Pompey and its wall paintings. The central compositions became increasingly small, encapsulated in round, oval, or square medallions, some of which even looking like cameos. The decoration has an intense polychromy, with a prominent white background and sometimes imitating wallpaper. The new iconographic repertoire includes plumes, flying birds, peacock feathers, branches, ribbons, and urns. The painting is less dense, with the loss of heavy-looking volumes, seeking a watercolor effect, with scrapings particularly in the yellow color to convey a sense of lightness (Pereira 1998; Câmara 2005).

At this point, tiles were integrated in a wider decoration scheme which involved painting, elaborated plaster works, and frescos, so they would sometimes not be the main focus. Chronologically, this style comprises the reigns of Queen Mary I (r. 1777–1816) and the early reign of John VI (r. 1816–1822), and since he assumed the regency in 1792, the period is also known as Regency style. Geographically the Lisbon area was the one with the most tiles, still in the wake of the reconstruction effort, with the best example being the tile panels of the Royal Palace of Queluz. Brazil also holds important examples, especially since the Portuguese court moved to Rio de Janeiro in 1807 following the French invasions (Pereira 1998).

Adding to the Lisbon cantered distribution of these tiles is the establishment of the first pottery factory by the Marquis of Pombal in 1767, the Real Fábrica de Louça do Rato (eng. Royal Factory of Rato). Its production was not prolific in tiles in a first stage until 1771 when the management fell on Sebastião de Almeida, son of Valentim de Almeida the tile painter we have already mentioned. For the most part, the factory produced the pattern tiles mentioned above. It is very hard to distinguish between the early factory tiles and the traditionally made ones since the technique and technology were roughly the same, with the names of Francisco de Paula e Oliveira and Francisco Jorge da Costa as the most prolific and important tile painters of the period (Meco 1989; Câmara 2005).

Conclusion

The first tile production context ever found in Portugal can be dated from the mid-sixteenth century, and, although this paper focuses exclusively on sixteenth- to eighteenth-century productions, tile production started much earlier in the thirteenth century and subsists until today. Tiles are decorated during this period with different styles, and despite the chronological organization, a new tendency does not annul the previous immediately, and we assist to a progressive change of style. However, older tiles are frequently replaced by newer ones, and this is one of the reasons why it is difficult to find well preserved sixteenth-century tiles.

The expansion of the type of building decoration followed the Portuguese around the globe, and, as aforementioned, they are everywhere to be found in Portuguese former colonies such as Cape Verde and Brazil. However, there are documental and archaeological evidence that these were exported to other countries such as England. London port books reveal the entrance of tiles from Lisbon, Vila Nova, and Coimbra during the seventeenth century revealing that these were in fact appreciated, although it is impossible to actually know what type of decoration was appreciated. The only Portuguese tile found in this country is a pattern tile.

These were frequent decorative solutions in palaces, churches, and convents; however, they could have been used in smaller houses as well, although archaeological evidence is not enough to conclude to what extent was a middle-class house decorated. How did people react to them when they entered a building with all the walls covered by polychromous pattern or a tale told in blue on white figures? Understanding the impact these tiles had in the daily life of Portuguese populations in Portugal and abroad is the next step.

Posnansky, Merrick

Jonathan R. Walz
Department of Anthropology and Archaeology Program, Rollins College, Winter Park, FL, USA

Basic Biographical Information

Merrick Posnansky's impacts on archaeology are numerous and enduring. His holistic, pragmatic, and inclusive initiatives helped to foster archaeology in Africa (Posnansky 1966a, b, 1969a; Posnanksy and DeCorse 1986) and in the Caribbean (Posnansky 1984). Posnansky's approaches to archaeology "prefigured the thrust of many postprocessual analyses of the 1980s and 1990s" (DeCorse 2004: 4). Since the late colonial era, Posnansky worked to enable university archaeology programs and to treat and reorient museums in Africa, making them living institutions with a mandate to serve the public. Posnansky's professional contributions in 11 countries have been recognized with numerous accolades, including the J.C. Harrington Medal in Historical Archaeology from the Society of Historical Archaeology. He is a Fellow or Honorary Fellow of the Society of Antiquaries in London, the British Institute in Eastern Africa, and Rotary International.

Born in Bolton, England, in 1931, Posnansky grew up in a small Jewish community during the interwar era. As a young man, he developed an interest in ancient coins. At age 18, Posnansky won an Open Scholarship to attend the University of Nottingham. After graduating, he completed a Diploma Course in Prehistoric Archaeology at Cambridge University. And, in 1956, Posnansky earned a Ph.D. in History from the University of Nottingham, under the supervision of the distinguished geologist H.H. Swinnerton. During his training and early in his career, Posnansky excavated prehistoric and medieval period sites in England, Wales, and France with archaeologists of renown, including Glynn Daniel and André Leroi-Gourhan. In 1956, Posnansky accepted an offer by Louis Leakey to work as the Warden of Prehistoric Sites in the Royal National Parks of Kenya.

Since the late 1950s, Posnansky's work focused on African archaeology, museums, and heritage education. After two years in Kenya, he transitioned to Kampala as Curator of the Uganda Museum and Head of Uganda's Department of Antiquities. In 1959, he was the first archaeologist in sub-Saharan Africa to take African university students on excavations. After a period as Assistant Director of the British Institute in Eastern Africa, Posnansky joined Makerere University College then affiliated with the University of London. In 1962, he taught the first university classes in African archaeology. A founding figure in historical archaeology, Posnansky integrated oral traditions into interpretations of Bweyorere and Bigo, ancient capital sites in Uganda (Posnansky 1966a, 1969b). In 1967, he and his wife, Eunice, left Uganda, fleeing the political turmoil caused by Idi Amin. At his next job post as Professor of Archaeology at the University of Legon in Ghana, Posnansky developed the first full academic program (B.A. to Ph.D.) in African Archaeology. He further launched an ethnoarchaeological study of a historical village in Ghana (Posnansky 2004) and completed numerous museum and cultural heritage projects in West Africa. In 1977, Posnansky joined the History Department at UCLA. He subsequently served as Chair of the Archaeology Program and Director of UCLA's Center for African Studies, the latter for 13 years. While at UCLA, his research expanded to Togo, Benin, and the Caribbean. Posnansky is a founding figure in African diaspora archaeology (Posnansky 1984).

Major Accomplishments

Posnansky's publications on urbanization, trade, oral traditions, art, museums, and education in Africa helped to reshape informed representations of Africans. His devotion to building culture histories where none previously existed; attending closely to cultural context; recognizing, valuing, and valorizing oral traditions; and applying

multiple sources to solve scholarly questions mark Posnansky as visionary. In his capacities as a curator and administrator, Posnansky developed archaeology programs at universities and trained African and American archaeologists. Professor Posnansky retired from UCLA in 1998 but remains active in the archaeology community, as he continues to write about and promote Africa, Africans, and their pasts.

Postcolonial Archaeologies

O. Hugo Benavides
Fordham University, Bronx, NY, USA

> Cruso raised his head and cast me a look full of defiance. "I will leave behind my terrace and walls," he said.
> "The will be enough. They will be more than enough." And he fell silent again. As for myself I wondered who would cross the ocean to see terraces and walls, of which we surely had an abundance at home; but I held my peace. (Coetzee 1986)

Introduction and Definition

> The past is never dead. It's not even past.
> (William Faulkner, Requiem for a Nun)

Since the 1960s, closely linked to the struggles of national liberation, anticolonialism, civil rights, and student uprisings, there has been a growing concern with the politics of domination in the West's liberal project of academic and intellectual production (Foucault 1980). Specifically in anthropology, and archaeology, this was marked by the presence of (so-called) natives in the subject-production of the discipline, natives which until then had been completely excluded from this noble enterprise other than as objects (and not subjects, creators) of knowledge. This particular political process highlights anthropology's origin as a colonial enterprise. In varied manners, the disciplines of anthropology and archaeology are still essentially invested in reproducing global knowledge in ways that structure us and others. In the process, such reproduction of global knowledge reconstitutes the West as the arbiter of world knowledge (Baldwin 1984).

The postcolonial enterprise marked less the inclusion of natives as the recognition of the central role that these marginalized groups (and identifications) had already played in the excavation (both literally and intellectually) of the past. This postcolonial reconfiguration had dif-

fering embodiments throughout the globe, from a politically combative Archaeology as social science tradition in Latin America, the political power of original populations communities from Polynesia to the Americas, and even the creation of the World Archaeological Congress to better represent archaeology as a real global endeavor.

Historical Background

One of the biggest impacts in the development of postcolonial archaeologies is the successful struggle of large indigenous communities throughout the world. Indigenous peoples of many nation-states have reached a new level of political discourse that demanded a shift in the conceptualization of traditional Indian identity, offering a more autocritical definition of themselves (Varese and Kearney 1995). This trend is related to the globalization processes affecting the world in general, particularly what Escobar (1995) has called the post-developmental phase of history. Post-development economies are based on flexible manufacturing and service industries organized on a global scale to take advantage of the most competitive source of supplies labor and market. Not surprisingly, workers in these economies receive low wages, no benefits, and no job security, all factors which contribute to an increasing informal economy.

One of the key components of these economies is transnational corporations that make of the international arena their economic playground. They expand the multinational corporation's role to retrieve raw materials and labor from third-world nations, reaching into the least unexplored regions of the world. It was precisely these marginalized regions to which the indigenous populations had been pushed into during the initial development period of the 1950s and 1960s. This new transnational influx into regions, such as the tropical forests of the Amazon, as well as those in Asia and Africa, has made many indigenous groups into a type of "development refugees." Faced with no alternative areas into which to retreat, indigenous group have been more willing than ever to go on the offensive and assert their rights.

Transnational corporations are highly influential in modern economies, but they are not the only transnational characteristics present. For instance, many indigenous populations do not live in a single nation-state, but rather occupy regions that crosscut two or more countries. The globalization process and the new forms of postmodern capitalism have also produced a long-term migration of indigenous people into urban centers of both their native countries or major industrialized nations like the USA and Europe (e.g., there are large-scale migration of indigenous populations from Mexico living in the United States today). The fact that today indigenous communities' main antagonist are transnational forces, outside of the control of national governments, has forced many indigenous groups to work with transnational sectors from the first world as well.

All of these globalization processes, such as flexible capital, increase of informal economy, transnational corporations, and the internationalization of social movements, have contributed to the reworking of indigenous identities that go beyond any previous traditional or strictly modern categorization. Varese and Kearney (1995: 219) point out that Indian communities

> who were formerly marginalized are now actively engaged in establishing a transnational civil society in an effort to bypass state mediation and to situate themselves in a global civil society while maintaining strong ethnic, cultural, and local loyalties that contest their own nation-state authority and hegemony.

In archaeology, this native conundrum was marked by a significant paradigmatic shift, away from the (now) traditional postulates of the new archaeology and towards a more relative understanding of the study of the past marked by a post-processual archaeology. As a postmodern enterprise, post-processual archaeology was an umbrella term that marked a host of interests, endeavors, and claims that differ significantly but still vehemently share a more complex understanding of the past than its positivistic ancestors. In this manner, archaeology, as part of the Western academy, had made way for numerous groups of

third-world scholars that no longer could be kept to the margins of intellectual production and many times marked the pace of new Western fields of knowledge (e.g., Said 1989; Spivak 1999).

This allowed for many to enunciate the postcolonial project as that of the simplistic inclusion of "native" scholars to the Western enterprise of archaeological research. Although more inclusive than its previous Western embodiments, this project of inclusion fails in quite an essential manner. This cultural undertaking elided the greater paradigmatic implication that it was less about opening spaces to native scholars in as much as the fact that these (supposedly) non-Western scholars had already erupted in a central manner into the scene. Perhaps more importantly, it further overlooked the fact that natives had always played a fundamental role in the production of the world's past, not only as creators of the archaeological sites and making up most of the crews that excavated any of the sites, but also that even in these reified Western territories, the past had always been about natives, elusive natives, that were erased from the intellectual landscape as fast as they were hailed at conferences, international exhibitions, and museums.

Key Issues/Current Debates

But no doubt, one of the more complex findings of postcolonial archaeologies was that the postcolonial project meant recognizing that the colonizer's past is also always that of the colonized, and vice versa. The intellectual commitment of postcolonial archaeologies is, therefore, not only about, literally, excavating a buried past of one oppressed group or community but rather to understand how that past, buried and later reconfigured, is an essential part of everybody's past and history. It is this particular kind of political commitment of third-world archaeologists and the uprising of native communities (and/or original population) all over the world that marked two very different postcolonial ways of connecting to the past, while still highlighting archaeology's essential political enterprise.

At a very basic intellectual level, these postcolonial approaches marked an opening to reidentify the archaeological landscape in the continent with markers of gender, sexuality, race, and class in ways that had not been possible before (Silverblatt 1987; Trexler 1995; de la Cadena 2000). But this new way of envisioning the past also manifested a renewed interest in colonial archaeology, again, not just for the reproduction of a European other but rather as a detailed study of the hybrid consolidation of the different original nation-states (Hall 1987).

This development of historical archaeology highlighted another area of postcolonial focus, the indivisible fusion of native and other, European, Arabs, and Africans (among many other groups), in the reproduction of new populations. This particular historical archaeology approach marks one of the, or even perhaps the, most interesting areas of contemporary research, one of ideological discursive practice.

As mentioned above, the postcolonial archaeological project was not content with merely including natives into the research enterprise, recognizing the political commitment of archaeological discourse, or even the political emancipation of historically oppressed racialized groups but rather the recognition how all of these elements are caught within the web of our own global historical production. That is, we are historical subjects in the making that are fed by continuous discursive practices about the past that can never fully escape our ideological repositioning. In this manner, one of the greater contributions of a postcolonial enterprise is to actively shy away from images of well-intentioned natives or native-saving agents and rather to recognize the global (neocolonial) landscape in which we all work and live in.

In the archaeological landscape, this postcolonial tradition was marked by new journals and publications that looked to reconfigure the manner of reproducing archaeological knowledge no longer as a nostalgic look to the north but one embodied with complete agency from the south (see Van Broekhoven 2010). This same ideal is behind cultural projects at many archaeological sites that are interested in furthering interdisciplinary research by incorporating the native other. And yet, these archaeological projects have

attempted to be necessarily aware that even these new postcolonial conundrums could not fully escape the historical conditions of our times, a history not of our making but ours nonetheless. And rather that these new re-foundational shifts about the other are necessarily responding to a global market that looks to reify difference as the essential cultural commodity of the twenty-first century (Hall 1987).

Unlike previous schemes of global domination, the transnational forces at work today are less about eradicating difference (at least no longer in explicit genocidal fashions) but rather about transnational capital essentializing cultural difference as a mechanism of maintaining similar forms of racial differentiation and hierarchies. In the archaeological landscape, this development imperative (to support and funds natives throughout the world) has quite complicated configurations. In this regard, postcolonial archaeologists have to not only seriously contend with transnational forces (e.g., oil, NGOs, transnational companies) that weigh in multiple ways upon their understanding of the past but also quite uniquely understand themselves as a social and political embodiments of these greater global forces at work.

International Perspectives

In Latin America, the postcolonial configuration meant the powerful commitment to an explicit political identification with the archaeologist's role of researching the past was no longer contained within an academic heading but rather marked a direct manner to connect to the Indian and colonial legacy of the American continent's history. Excavating the Latin American past was directly connected to challenging the neocolonial conditions of the present. In that sense, one now excavates one's own past, a past that had been dutifully denied and repressed by the Western-inspired national governments and the "objective" national histories of each of nation-state (see Lumbreras 1981; Vargas 1990).

As an example of a postcolonial archaeology, there are two initial factors on which this Latin American social archaeology approach is based: the first is the strong social and political commitment that an archaeologist, as a social scientist, feels towards the community; the second factor is the historical materialist paradigm that many archaeologists embrace as a tool to analyze and understand history (Bate 1977, 1978). These two factors enable the social archaeologists to reconstruct history and see its continuity and value in contemporary society. This alternative form of archaeology proposes to destroy the false theory-praxis and science-advocacy dichotomies and argues that the archaeologist has an important responsibility and plays a pivotal part in situating historical knowledge at the center of the continent's social struggle. In essence, social archaeology proposes a more political and socially relevant way of addressing our inquiries into the past.

Furthermore, social archaeologists engaged in this approach see themselves linked to the past that they are interpreting. Rather than seeing themselves removed from their research, they see themselves as the end product of this historical process. Not only does this not interfere in the study of the past due to some limited, ethnocentric, or nationalistic claim, but rather, it demands an even more objective understanding of it. This objectivity is of utmost importance because the past is directly tied to whom we are as a people, and this knowledge is needed for the historical construction of the continent's present and future.

Another explicit postcolonial engagement with the past is the "alternative" national history proposed by the single most powerful social movement today in Ecuador and largely represented by the CONAIE (*Confederación de Nacionalidades Indígenas del Ecuador*), which has been able to bring together the majority (although not all) of the Indian community in their collective grievances and struggle against the Ecuadorian state. These grievances range from land claims to controversial constitutional amendments. This

discussion is mainly interested in the CONAIE's own reading of the pre-Hispanic past which legitimizes its struggle and has visibly contributed to it becoming a viable political force in the country.

The two most important claims by the CONAIE that constitute a counter hegemonic discourse to the official history are its demand for territorial self-determination for each Indian nationality and a multinational state. The demand for territorial self-determination relates to both differing understanding of the land, nationalism, and economic development. As Karakras (1990: 5 and 20) explains:

> We are peoples, we are nationalities, we have our own national processes. . . . The Indian peoples are interested in making the proclamation of auto-determination a reality and in taking their historical destiny into our own hands.

The land is seen as an integral part of Indian culture and essential for constructing an independent livelihood, just as a mother is essential for the nurturing of her children. The regaining of the land itself is essential to maintain their culture and developing it, it is a vital necessity (Karakras 1990). This is why the CONAIE presents its claim for the land as an integral part of their demands, reaffirming that the land.

In contrast, the present Ecuadorian state strives to continue its century-long project of constructing a single homogenous Ecuadorian nationality and to locate all the nation's natural and commercial resources under a central state authority that will oversee its development. The Indian proposal presents opposite demands – it wants to preserve native lands, customs, and environment from any outside exploitation, including from that of the central state. It in no way shares the dominant view of capitalist production as the way to prosperity but rather sees it as further contributing to the destruction of their lands and cultures. For the CONAIE, only a communal and autonomous self-government would contribute to the improvement of each national group and, therefore, of the central state (CONAIE 1989).

The second demand of the CONAIE for a multinational state entailed a reform of Ecuador's constitution and defined the state as plurinational in character. According to the CONAIE, this was necessary because each Indian community is a nationality in its own right, with its own culture, heritage, traditions, and language. This constitutional reform, in this manner, did not only benefit the Indian nationalities but also other oppressed groups like Afro-Ecuadorians that could gain from the restructuring of a more pluricultural and democratic state apparatus (CONAIE 1998).

This proposal is a reformed position from previous Indian stances because it recognizes the reality of the Indian nationalities caught within the Ecuadorian nation-state. It also recognizes the complex makeup of the country and the presence of other ethnic and racial groups. In contrast to earlier positions, it appropriates Western concepts to serve Indian interests. A multinational state also inherently speaks to the right of each nationality to autonomous self-determination (CONAIE 1989, 1997). This self-determination is understood as permitting legal control over their own societies within the structure of a single more representative and democratic state: "that is, you can be of a different nationality but belong to the same state" (Karakras 1990: 23).

Both of the CONAIE's main demands are potentially counter hegemonic, yet it is clear that the state and transnational forces will always be striving to neutralize each of these radical changes, or even worse reincorporate them into their own redefinition of the global landscape.

Future Directions

> To overhaul a history, or to attempt to redeem it – which effort may or may not justify it – is not at all the same thing as the descent one must make in order to excavate a history. To be forced to excavate a history is, also to repudiate the concept of history, and the vocabulary in which history is written; for the written history is, and must be, merely the vocabulary of power, and power is history's most seductively attired false witness. (Baldwin 1990)

The contemporary setting highlights processes where interest groups like oil companies decimate

contemporary Indian communities while being forced to invest in recuperating their ancestral pasts or quite similarly the support of environmental and other NGOs that coincidentally continue to reify racial hierarchies in ways that can no longer be deemed innocent or well intentioned. One of the greater contributions of a postcolonial archaeological enterprise is to actively shy away from images of well-intentioned natives or native-saving agents and rather to recognize the rocky boat (or ship of fools) that we are all equally members of. That is why new concerns of the past, such as the *Taller Etnohistórico Andino* in Bolivia or the CONAIE's lack of concern with direct ancestral claims to archaeological site, are both equally valid manners to recognize the complex manner in which we are one and the other, Western and not, at one and the same time (Kincaid 1997).

In the same token, it is this necessity to recognize that any active refusal to accept our complicity in this pervasive Western discourse of differentiation could only continue the geno- and ethnocidal paths that have brought us to reflect at this place (Malkki 1995). Perhaps it is the recognition that we are one and the same, from an "odd mixture of continents and blood, of here and there, of belonging and not" that may provide the most singular forms of transient agency (Kureishi 1990: 3). As James Baldwin (1990: 481) states: "Our history is each other. That is our only guide. One thing is absolutely certain: one can repudiate, or despise, no one's history without repudiating or despising one's own." And the postcolonial archaeologies' mind-set means recognizing that the colonizer's past is also one's own and that the opposite is true as well.

Introduction

Archaeology in Cambodia has grown exponentially since the end of the Khmer Rouge period and the establishment of the Paris Peace Agreement of 1991. Several institutions are responsible for overseeing this growth including the APSARA Authority, the Ministry of Culture and Fine Arts (MOCFA), the Royal University of Fine Arts (RUFA), and more recently the Royal Academy of Cambodia (RAC). This entry discusses the roles these institutions have played in the revival of archaeological research in Cambodia, Cambodian perspectives on the advance of archaeology in their country, and suggestions for future goals of archaeological research in Cambodia.

Historical Background

Cambodian arts and culture were reinvigorated in 1953 when Cambodia received independence. One focus of this period was an attempt to understand and define "modern Khmer culture" (Daravuth and Muan 2001). In 1965, the Royal University of Fine Arts (RUFA) was established in Phnom Penh as the first truly Cambodian university and included a Faculty of Archaeology staffed by Cambodian instructors that had studied and trained in France (Daravuth and Muan 2001). By 1971, plans were made for the construction of a large conference hall and space for a library, classrooms, and research center on an expanded Royal University of Fine Arts campus (Key 2001 [1971]). Unfortunately, these plans were not implemented due to the civil war and the fall of Phnom Penh to Khmer Rouge soldiers in 1975. Only three Cambodian archaeologists in Cambodia survived the Khmer Rouge period (Griffin et al. 1999).

Key Issues

As archaeology in Cambodia was reestablished, it was recognized that government bodies overseeing archaeological patrimony were needed. Additionally, training of new archaeologists was necessary to provide human resources for these institutions.

Archaeological Patrimony: The APSARA Authority

The APSARA (Authority for the Protection and Safeguarding of the Angkor Region) Authority was born out of a need to protect and conserve the sites in the Angkor region following the Khmer Rouge period (for a detailed history on the formation of APSARA, see Choulean et al.

P

1998; Chau Sun 2006). Just 1 year following the signing of the Paris Peace Agreements, the Angkor region was conditionally inscribed on the UNESCO World Heritage List. The sites within the "Perimetre de Protection" included Angkor Wat, the Bayon, Roluos, Banteay Srei, and others. The listing was provisional provided that Cambodia meet several conditions. These were fulfilled in 1995, and Angkor was inscribed permanently on the World Heritage list. In the same year, the APSARA Authority was established by royal decree and was tasked with the management and protection of the region of Angkor and Siem Reap. As Angkor was becoming a major tourist destination, APSARA primarily focused on preventing illegal construction projects. However, it was also important that APSARA become increasingly autonomous, in order to provide "the institutional structure vital for nurturing the Cambodian expertise required for managing the site over the longer term" (Winter 2007: 51).

Currently, the APSARA Authority describes their mission as "Protecting, maintaining, conserving, and improving the value of the archaeological park, the culture, the environment, and the history of the Angkor region as defined on the World Heritage List" (APSARA Authority 2005). The APSARA Authority contains several departments that oversee these various concerns. These include two departments dealing with Monuments and Archaeology, the Department of Angkor Tourism Development, the Department of Urbanization and Development of the Siem Reap and Angkor region, a Department of Demography and Development, and a Department of Water and Forest Management. Archaeological research and conservation of monuments is undertaken collaboratively between the APSARA Authority and various international organizations. All international projects must include training of Cambodian students as part of their project as well as collaboration with APSARA staff and experts.

As Cambodia's popularity as a tourist destination increases, APSARA has had additional challenges in managing tourism and development in Siem Reap, as well as interacting with the local population, while also following their initial goal of protecting and conserving sites. Recent archaeological research shows that the Greater Angkor Region is approximately 1000 sq. km, much larger than the initial zones included in the World Heritage listing (Fletcher et al. 2007). These additional archaeological features, which include mounds, channels, and water features, are often found in rural areas where people live and work. Several thousand people also live and work within the archaeological park itself. The rapid expansion of Siem Reap as a tourist center has also had environmental consequences especially relating to water management, which has become a new priority (Munthit 2008). Growing numbers of tourists are increasing the wear and tear on the stone and brick monuments, which has led to the closing off of some areas of temples. As tourist numbers increase, the APSARA Authority will continue to see their responsibilities grow. In turn they will have to balance protection, conservation, and research of the archaeological sites under their purview while also managing the needs of the local community and facilitating the needs of tourists, whose dollars are so crucial for the Cambodian economy.

Archaeological Patrimony: The Ministry of Culture and Fine Arts (MOCFA)

The Ministry of Culture and Fine Arts is the other main body responsible for the protection and research of archaeological sites in Cambodia. MOCFA was established by royal decree in January 1996, and its primary responsibilities include the development of culture and fine arts as well as promoting Cambodia's diverse cultural heritage. Archaeological oversight falls under the General Department of Cultural Heritage and four subdepartments: Archaeology and Prehistory, Antiquities, Museums, and Preservation and Conservation of Ancient Monuments. MOCFA is responsible for all archaeological sites in Cambodia except for the sites located in Siem Reap province and the sites located in the region controlled by the National Authority of Preah Vihear in Preah Vihear province. These include archaeological sites such as temples, and pagodas, as well as ancient mounds, bridges, canals, water reservoirs, and roads.

One of the primary goals of the MOCFA is the broad promotion of archaeological research.

Local archaeologists are encouraged to collaborate with foreign institutions and researchers to conduct survey, excavation, and restoration and preservation projects. The MOCFA is also concerned with documenting all archaeological sites on land, as well as those underground and underwater, in order to highlight their importance for Cambodia's national cultural heritage. Recently, more than 4000 archaeological sites have been documented, mapped, and zoned in a collaborative project between MOCFA and the École Française d'Extrême-Orient (EFEO) (Bruguier et al. 2007). Some of these sites have also been excavated or restored in collaborative projects with local experts and international researchers through external financial support. Prior to starting such projects, MOCFA requires the collaborative organizations to create an agreement clarifying the project plan, its schedule, and budget. The MOCFA also emphasizes the importance of heritage education, as the education of local people, officials, police, monks, and students is key to protecting cultural heritage in Cambodia. In this vein, some sites are slated for development as tourist attractions, and the MOCFA intends to open as many provincial museums as possible.

In addition to these smaller sites, the MOCFA is currently preparing documents for UNESCO and the World Heritage Commission to submit Sambor Prei Kuk to be included on the list of World Heritage sites. If accepted, a Sambor Prei Kuk Authority would be created as a separate unit within the MOCFA. Other sites slated to be nominated for World Heritage status include the Banteay Chhmar temple complex, the temple of Preah Khan of Kompong Svay, Beng Mealea and Koh Ker temples, Phnom Chisor temple, and the site of Angkor Borei. While the MOCFA does not have direct control over the other World Heritage sites of Angkor and Preah Vihear temple, it does work closely with both APSARA and the National Authority of Preah Vihear.

Despite the progress made in recent years, the MOCFA still has many challenges related to the destruction of archaeological sites and illicit trafficking of cultural property. Recently, the acquisition of land by powerful businessmen and institutions has caused the destruction of many archaeological sites. Furthermore, local people often do not understand the importance of preserving sites, which can also lead to looting. Unfortunately, the MOCFA does not have enough resources to address all of these problems or investigate crimes. Additional difficulties include assessment and cultural valuation of various art objects, as there is not enough equipment to appraise the materials. Looting, stealing, and illegal trafficking of art objects in Cambodia are problems that make the protection and conservation of sites and objects complicated.

Archaeological Training: The Royal University of Fine Arts (RUFA)

The Royal University of Fine Arts (RUFA) has played a central role in producing new archaeologists, both before and after the Khmer Rouge period. Although RUFA was reopened in 1980, the first courses offered were only in the School of Fine Arts. It was not until 1989 that RUFA was awarded its full university status and the Department of Archaeology was reopened by its surviving alumni, including professors Chuch Phoeurn and Pich Keo. However, the department faced a great challenge due to limited human resources. The curriculum was based on prewar coursework, which included classes on Khmer history, epigraphy, art history, ethnology, and archaeology. Other courses were focused on civilizations and cultures directly related to Cambodia, such as Indian classical languages and art history, and other Southeast Asian cultures and civilizations including the Cham, Javanese, Burmese, and Thai. Also critical to the curriculum were study trips to major archaeological sites, consultation with national and international experts, as well as internships with various conservation organizations and archaeological institutions.

With funding from the Toyota Foundation via UNESCO from 1995 to 2002, the Department of Archaeology drastically improved its human resources by adding national and international experts to the faculty (UNESCO 2002). Graduates of the 1994 RUFA class and junior faculty members were assigned as teaching assistants for each major topic. It was hoped that these teaching assistants and junior scholars would gradually replace their international professors and reduce the department's reliance on foreign assistance.

However, this hope was not realized, as the department lacked funding to maintain a large faculty after UNESCO ended their assistance in 2002. Fortunately, one unexpected and positive outcome of the project was the production of a series of highly competent Cambodian archaeologists, who were students of the UNESCO-funded faculty. Students who earned their degrees from 1995 to 2002 have filled positions in most of the cultural resource management institutions in Cambodia, such as MOCFA, the APSARA Authority, the Royal Academy of Cambodia, and other archaeological and conservation projects. Additionally, several students have continued their education by earning doctoral degrees at institutions in Cambodia and abroad.

Currently, RUFA is beginning to renovate and expand their existing facilities in order to provide more classroom, lab, and library space. Additionally, a group of scholars are working to develop a core curriculum for archaeology students. Despite these developments, RUFA continues to struggle with a lack of funding to support faculty and provide resources for students. Many RUFA alumni have volunteered to offer part-time classes or conference talks to current students. Despite the efforts of dedicated faculty, staff, volunteers, and alumni, RUFA needs additional financial support in order to provide adequate resources for its students and teachers. In spite of these challenges, a new generation of archaeologists has gradually increased and is able to respond to the demand for archaeologists and conservators in institutions such as the MOCFA, APSARA, and Preah Vihear authorities. Since the opening of the twenty-first century, more and more Cambodian archaeologists have gradually risen from field workers and trainees to become collaborators and colleagues in various international institutions in Cambodia and abroad.

Archaeological Training: The Royal Academy of Cambodia (RAC)

In addition to RUFA graduates, Cambodian scholars with advanced degrees are needed to train, teach, and lead research projects. With this goal in mind, the first government-sponsored master's and doctoral degrees were established in 2002 in the Department of Archaeology in the Institute of Culture and Fine Arts at the Royal Academy of Cambodia (RAC) in 2002. The goals of the program include the management and development of archaeological research, the collection and preservation of research finds, the documentation and distribution of research findings, and the expansion of cooperative relationships with other institutions, ministries, and national and international organizations related to archaeological research. During the first phase of this program, five master's and doctoral candidates were selected for training after a rigorous examination.

The program has now moved into the second phase, in which graduates of the program will focus on research with government support. One graduate has already completed his Ph.D. and two others are Ph.D. candidates. Several research projects have already been completed, including the Sre Ampil project (discussed below), mapping and excavation at the Choeung Ek Kiln Site, and most recently a project entitled "Archaeology Research and Management at Prasat Trapeang Prasat" funded by the Royal Government (Fig. 1). Conservation work is currently being conducted at Trapeang Prasat, an important yet unstudied temple located near the Dangrek Mountains in Udor Meanchey province, to preserve the historical and archaeological integrity of the site for future generations (Fig. 2). Conservation of this site will hopefully increase national and international tourism to the region and will provide an important benefit for the local economy.

Since 2002 RAC has organized national and international conferenc es with the joint support of the Royal Government and international institutions. In 2014, RAC, in collaboration with the MOCFA, the APSARA Authority, the National Authority of Preah Vihear, the National Committee of World Heritage, and other NGOs, will host the 20th Indo-Pacific Prehistory Association Congress in Siem Reap. In the future, the Institute of Culture and Fine Arts at the RAC will extend its research projects by seeking funding from both the Royal Government and other resources and expand its international relationships with joint research projects and additional international conferences.

International Perspectives

Currently, Cambodian archaeologists are working to define their role in shaping archaeological research in their country. Since Cambodia has reopened for archaeological research, there have been many international research institutions working in Cambodia. Cambodian archaeologists have had many opportunities to join these projects and gain experience for their future careers. However, these projects are often run and directed by foreigners, and Cambodians are often only hired as research assistants. In many cases, the research findings, archaeological materials, and results remain under the control of the director of the project. Under these circumstances, Cambodian archaeologists are not always equal collaborators.

It is for this reason that opportunities for Cambodian-led research projects and in-country

training, such as the RAC advanced degree program discussed above, are so important. One successful Cambodian-led project is the Sre Ampil project, a 2-year program funded by the Center for Khmer Studies with archaeologists and students from RUFA and RAC. Cambodian archaeologists and students conducted excavations at the site of Sre Ampil and worked with local villagers to construct a site museum, which includes both artifacts from excavations and objects donated by villagers (Fig. 3). The Sre Ampil archaeological site will also be used as a permanent field training site for RUFA archaeology students and possibly for students in anthropology and tourism studies from other universities (see Phon and Phon 2009). Another step forward in the process of increasing indigenous archaeological research is the establishment of the Khmer Archaeological Society (www.khmeras.org). This Cambodian-led NGO established by Mr. Phon Kaseka seeks to preserve past and present cultural heritage, including the heritage of minority groups such as the Cham and Kuoy. In this way, Cambodians are beginning to take a leadership role in the practice of archaeology in their country.

Future Directions

Archaeological research in post-Khmer Rouge Cambodia has made great strides since the country reopened for archaeological research in the 1990s. Nevertheless, there are still several areas where improvements can be made. First, it is recognized that many archaeological sites in Cambodia are still vulnerable to looters or development. Cultural resource protection and education and implementation of heritage law is lacking in Cambodia. Therefore, a focus on archaeological site preservation and salvage excavations is needed. Furthermore, local involvement and education is a crucial aspect in protecting against site destruction. As part of this goal, it is important to continue with the construction of site museums for the display of artifacts collected at the site. Retention of cultural treasures by the communities in which they are found is good for reinforcing cultural identity, local morale, the economy, and the education of villagers and tourists who will jointly support the museums. This is currently an important goal of the MOCFA, and several local site museums have already been constructed. Site museums and the recognition of important sites outside the Angkor region would also reduce problems related to over-visitation of the principal sites in Angkor. Tour agencies currently neglect other areas in the country where there is tourism potential. Tourism development at these would attract national and international visitors to spend time in other parts of Cambodia beyond Angkor and increase tourist dollars. It is also hoped that training programs for students at RUFA, RAC, and other universities would allow them additional opportunities to practice their skills and assist with job placement after graduation. Lastly, it is essential that Cambodian

archaeologists continue to develop relationships with other international scholars, especially those in other Southeast Asian countries. Hopefully, with increased in-country education and training, Cambodian archaeologists, in partnership with foreign collaborators, can lead the way toward achieving many of these objectives.

Post-Medieval Archaeology

Jacqueline Pearce
Museum of London Archaeology Service, London, UK

Brief Definition of the Topic

Post-Medieval Archaeology is the journal of the Society for Post-Medieval Archaeology, founded in the UK in 1966. The Society takes a lead in promoting postmedieval archaeology in Britain and advises government and other national bodies. The journal publishes an annual roundup of fieldwork undertaken in the UK and an annual report of significant finds recorded by the Portable Antiquities Scheme. In addition, the biannual journal aims to publish a diverse range of articles and shorter notes on both British and international archaeology. Its scope is the material evidence of European society, wherever it is found throughout the world, in a period that saw the transition from medieval to industrial society and the foundation of the modern world on new Renaissance and Reformation values, marked by the shift from collective to individual mentalities; increasing social segregation; new notions of privacy, family, gender, and space; global expansion; and revolutions in the modes and scales of production. The journal fosters a multidisciplinary approach to the past, encouraging use of material, textual, iconographic, and scientific evidence, as well as engaging in the latest theoretical debate. Its chronological remit extends right up to the present day. The European Reference Index for the Humanities (ERIH), published by the European

Science Foundation in 2007, places *Post-Medieval Archaeology* in its category "A": high-ranking international publications with a very strong reputation among researchers of the field in different countries, regularly cited all over the world. Details on submission procedures can be viewed on the Society's website at http://www.spma.org.uk/journal.php.

Post-Medieval Archaeology (Europe)

Chris King
Department of Archaeology, The University of Nottingham, Nottingham, UK

Introduction

Post-medieval archaeology is the term commonly used in Europe for the study of post-CE-1500 society, although there remains debate over the chronological definition of the subject at both its beginning and end points. The archaeology of post-medieval Europe is potentially a vast subject, encompassing a huge variety of material remains across a remarkably diverse linguistic, political, and cultural environment. It is a relatively young branch of archaeology, only really emerging as a distinct field of practice in Britain in the decades after the Second World War. Here, it is now a well-established feature of academic research, national and regional heritage management policy, and developer-funded commercial archaeology. On the Continent, post-medieval archaeology developed as a natural progression from the study of medieval archaeology, and it is only since the 1970s that archaeological investigations of post-CE 1500 remains have been regularly undertaken and published, most notably in Northern and Western Europe. There are still very few academic posts dedicated to post-medieval archaeology on the Continent, and most post-medieval archaeological research is conducted within the context of development projects. In Central and Eastern Europe and the Mediterranean countries, post-medieval archaeology remains underdeveloped as a distinct subdiscipline, although this is now beginning to change. Cross-European and global perspectives are increasing within the subject, and a wider range of methodological and interpretive approaches are being advocated by leading practitioners in both Britain and the Continent.

Definition

Both the chronological start and end points of the term "post-medieval" have been the subject of widespread debate in European archaeology. The term is used by European archaeologists for the study of post-CE-1500 material remains. It is often used in contrast to the term "historical archaeology," which was first developed in the USA for the investigation of sites of European colonial settlement. The latter term is now widespread internationally and used in two overlapping senses: firstly, as a definition for the archaeology of European settler societies in New World contexts (including North and South America and Australasia) as well as their interaction with and impact on indigenous peoples and, secondly, as a catch-all term for the archaeology of

the last 500 years. Many accounts maintain that this period is dominated by European imperialism and the spread of global capitalism and that archaeologists should seek out these phenomena in specific local contexts. However, European archaeologists often counter that both the term "historical archaeology" and the interpretive focus on colonialism and capitalism are inappropriate for their area of study because widespread historical documentation exists for many European countries from the medieval period as well as the classical past, and because colonialism and capitalism were experienced in very different ways in Europe compared to the brutal colonization of New World territories. Anders Andrén has argued that post-medieval archaeology is one branch of a wider "historical archaeology" that encompasses the archaeological study of all literate societies (Andrén 1998). This too has its problems, given that many recently literate societies have well-established traditions of oral history, for example, in sub-Saharan Africa.

These debates highlight the distinctive intellectual traditions from which European post-medieval archaeology emerged. In contrast to American archaeology, which is based within the discipline of anthropology, in Europe the archaeological study of the more recent past emerged gradually from the study of Roman and medieval archaeology, with strong connections to the disciplines of history, art-and-architectural history, and historical geography. On the Continent, the vibrant field of folk studies or "European ethnology" had an equally powerful effect on the early development of the discipline, manifested by the establishment of regional folk-life museums and collections of preserved historic buildings and implements (e.g., the open-air museum at Skansen in Stockholm (Sweden), founded in 1891) (Fig. 1). The growth of social history and the Annalés historical school in the mid-twentieth century, with its emphasis on the material realities of everyday life and the *longue durée* of landscape and cultural change, was a significant influence. This reflects the genuine continuity of the historical and archaeological record between the medieval and post-medieval periods. European rural landscapes and urban centers often have long histories stretching back to prehistoric, Roman, or medieval times, and many aspects of the post-medieval archaeological record, from material culture types to plans of buildings, actually originate in the preceding centuries. This means that European archaeologists often work across the medieval and post-medieval periods and are specialists in particular types of archaeological evidence (such as ceramics, glass, or buildings) rather than period specialists. However, the term

Post-Medieval Archaeology (Europe), Fig. 1 Reconstructed nineteenth-century buildings at Skansen living history museum, Stockholm, Sweden. (© Paul Courtney)

post-medieval was first used for the study of the sixteenth to eighteenth centuries only and is arguably less relevant to the growing focus on nineteenth-, twentieth-, and twenty-first-century archaeology. Some European scholars have advocated that "post-medieval" should be abandoned in favor of the more commonly accepted global terminology. They recognize that there is a need to investigate the dramatic changes occurring in post-medieval Europe while avoiding totalizing grand narratives which obscure the complexities of local, regional, national, and global cultures and connections (Hicks 2005).

While post-medieval is the term used by archaeologists, historians more commonly use the terms "early modern" for the period from the sixteenth to the eighteenth centuries and "modern" for the nineteenth century to the present day. The historiographical divide between the "medieval" and "post-medieval" or "early modern" period is a long-standing one in European historical and political thought. It reflects a widespread conception that the sixteenth century witnessed major transformative changes which clearly separate a traditional, feudal medieval past from the development of modern European society. These can be summed up as a series of large-scale historical processes and cultural watersheds, many of which would be expected to have archaeological expressions. Most notable among these could be considered the "Renaissance" of classical literature and art in fifteenth- and sixteenth-century Italy, the dramatic impact of the European Protestant Reformation from the second decade of the sixteenth century which saw the breakup of the unified Roman Church, the European discovery of the New World in 1492 and the establishment of European global empires, the early modern "scientific revolution" and the spread of Enlightenment philosophy and democratic politics, and, in the realm of the economy, the ascendancy of capitalism through agricultural and urban expansion, global trade, and the impact of eighteenth- and nineteenth-century industrialization. However, it must be recognized that these large-scale processes are essentially modern historiographical constructions which arguably have limited importance for many aspects of the archaeological and historical record. The start date of c. CE 1500 is an arbitrary convention which can conceal important elements of continuity within European social, economic, and religious life.

"Europe" is also a contested concept for this period. In the sixteenth century, Europe consisted of multiple fragmented polities and regional societies, containing a huge variety of languages and cultures. While there were certainly many connections between different areas of Europe, stimulated by trading networks and the important role of the Roman Church, it is debatable whether ordinary people would have shared many cultural affiliations with even regional neighbors, let alone any kind of pan-European identity. The early modern period saw the creation of the nation-states of contemporary Europe, which were in part shaped by new material and architectural expressions such as fortifications and nationalistic symbols. It is vital to remember that large-scale historical processes such as the Reformation or the rise of capitalism affected different regions and communities in different ways and at very different speeds, some being imposed from above, while others emerged organically from small-scale changes in everyday economic and social practices. Furthermore, because the development of post-medieval archaeology has been led by Britain and Northern and Western Continental Europe, there has been a tendency to marginalize the archaeology of other regions of Europe. For instance, in Eastern Europe and Russia, the Orthodox Church remained a major unifying force at the same time as Western European Christendom was becoming fragmented into Catholic and Protestant realms, while a major portion of Southeastern Europe and the Eastern Mediterranean remained part of the Islamic Ottoman Empire throughout the post-medieval period, drawing significant cultural influences from North Africa and the Middle East.

If c. CE 1500 is a widely shared start point for European post-medieval archaeology, there is much greater variety in when the period is considered to have ended. The first practitioners of the discipline tended to focus on the early post-medieval centuries. In Britain, the Society for Post-Medieval Archaeology was founded in 1966, emerging from the Post-Medieval Ceramic Research Group which had been established three

years previously, and the first issue of its journal *Post-Medieval Archaeology* appeared in 1967. The Society originally defined its remit as the archaeology of the period from c. CE 1500 to c. CE 1750, arguing that the mid-eighteenth century saw profound changes in the development of industry and society which made a natural cutoff point. At the same time, industrial archaeology had emerged as a distinct subdiscipline in the 1950s, with the Association of Industrial Archaeology being established in 1973. Many early advocates of industrial archaeology had a narrow focus on questions of technological development and the economic impact of industry, but there was a growing concern to record the ordinary experiences of industrial workers, and some advocated that industrial archaeology should be seen as the archaeology of the totality of society in the eighteenth and nineteenth centuries (Nevell 2006). The first synthesis of post-medieval archaeology in Britain by David Crossley concentrated on the early period, covering urban and rural landscapes, building types, material culture, and the evidence of early industrial production (Crossley 1990). In the past two decades, there has been much greater emphasis on the archaeology of the eighteenth and nineteenth centuries, in part stimulated by the influence of historical archaeology in the USA and Australasia, and this is reflected by the content of the most recent survey of post-medieval archaeology in Britain which continues to c. CE 1900 (Newman 2001). The Irish Post-Medieval Archaeology Group was established in 1999 and has published work on both early modern "plantation-era" archaeology and more recent industrial and urban sites. In Britain there has also been increased emphasis on developing archaeological studies of the recent past. This was initially stimulated by the recording of the First World War and Second World War military heritage and, since the late 1990s, has been extended to the study of Cold War sites and the application of archaeological approaches to contemporary (late twentieth and twenty-first century) material remains including council houses, tower blocks, protest camps, and graffiti (Buchli and Lucas 2001). The recently formed Contemporary and Historical Archaeology in Theory (CHAT) group provides a focus for this work. Recognizing these broad shifts in the methodological and thematic coverage of the discipline, in 2006 the Society for Post-Medieval Archaeology officially extended its remit to incorporate the archaeology of the period from c. CE 1500 to the present day.

Key Issues/Current Debates/Future Directions/Examples

The early focus within post-medieval archaeology in Britain was on developing typological studies of specific material culture categories (such as ceramics, glass, and clay pipes), which could be used for dating excavated sites and for studies of technology and production, and the publication of excavations, especially urban sites and industrial production (kiln or furnace) sites. The 1970s and 1980s saw the growth of "rescue" archaeology within the UK as urban centers were extensively redeveloped, and while much attention was focused on Roman and medieval remains, some important post-medieval sequences were excavated in towns such as London, Norwich, and Exeter. The 1982 televised raising of Henry VIII's flagship *The Mary Rose* from the Solent channel, and the public interest in the wealth of well-preserved organic material culture from the wreck, showed that post-medieval archaeology could be as highly valued as earlier periods, a point which was reinforced in 1989 during the major public controversy over the threatened destruction of the remains of the Elizabethan "Rose Theatre" on London's South Bank. In the mid-1990s, new legislation provided protection for both buried archaeology and listed buildings (Planning Policy Guidance Notes 15 and 16). This has had a dramatic impact on the study of post-medieval remains in Britain, which are now increasingly excavated and published as important parts of the archaeological sequence in their own right rather than being seen as later "disturbance." The study of post-medieval buildings was already well developed as an important subdiscipline following the foundation of the Vernacular Architecture Group in 1952, with the first issue of the journal *Vernacular Architecture* appearing in 1970. Studies of rural landscapes

and buildings have increased in number and scope, with a focus on the impact of the enclosure of medieval agricultural landscapes and shifts in settlement patterns in the eighteenth and nineteenth centuries (Newman 2001) (Fig. 2). Within Britain, there is now a strong conception that the "historic environment" encompasses the archaeology, buildings, and landscapes of all periods of the past, which should be protected and adapted to provide a meaningful "sense of place" for contemporary communities, although this is not always applied rigorously to later post-medieval structures which are often undervalued or taken for granted.

Since the early 1990s, a small number of post-medieval academic posts have been established in British universities, and scholars have advocated the integration of explicit archaeological theory and a greater plurality of interpretive approaches within the subject. Rather than seeing post-medieval archaeological remains primarily in terms of technological or economic change, they argue that material culture should be seen as meaningful within social relationships and social identities in the past – for instance, in terms of class, gender, ethnicity, or religion. One major area of focus for both academic and museum-based archaeologists is on the transition between the medieval and post-medieval periods. Studies of a wide range of material culture types including buildings, fortifications, ceramics, dress fittings, and metal toys show that there were significant elements of continuity as well as change in people's material environment. A focused study on the archaeology of the Reformation highlighted that religious change in sixteenth-century Europe involved both top-down and bottom-up transformations in belief and practice and that much older medieval religious culture was incorporated into new Protestant and Catholic religious cultures (Gaimster and Gilchrist 2003). Matthew Johnson studied changes in vernacular farmhouses, material culture, and the enclosure of rural landscapes in sixteenth-century Suffolk, England, arguing that they reflected the transformation of the social order through the rise of privacy and commodification, revealing the spread of capitalist socioeconomic relations (Johnson 1996). More recently, Sarah Tarlow has examined the material remains of eighteenth- and nineteenth-century Britain and argued that rather than simply reflecting capitalism, they are also a product of changing ideologies such as the widespread idea of "improvement," which stimulated new farming practices, the rebuilding of town centers, and the creation of institutions of "moral reform" such as workhouses and prisons (Tarlow 2007) (Fig. 3).

Post-Medieval Archaeology (Europe), Fig. 2 Excavations of eighteenth- and nineteenth-century farm buildings at Henllys Farm, Pembrokeshire, Wales. (© Harold Mytum)

In Continental Europe, post-medieval archaeology emerged more recently than in the UK and currently retains a focus on the immediate post-Reformation centuries. There are few dedicated academic posts in the subject, mainly concentrated in Germany and Scandinavia, and most post-medieval archaeological research is undertaken by archaeologists connected to urban municipalities, state heritage or archaeological services, or museums, within the context of development projects. In Germany, the subject was stimulated by the excavation of well-preserved

Post-Medieval Archaeology (Europe), Fig. 3 The Workhouse, Southwell, Nottinghamshire. Built in 1824 as a new type of institution within a reformed system of poor relief, it was designed to classify, segregate, and punish the "undeserving" poor. (© Chris King)

archaeological sequences from Hanseatic towns including Lubeck and Duisburg in the 1970s and 1980s (Krause 1992). The German Society for Medieval Archaeology *(Deutsche Gesellschaft für Archäologie des Mittelalters)*, which was founded in 1975, extended its remit to cover *Neuzeit*, or "the archaeology of the modern period," in 1990. In 2009 a new German and English open-access journal *Historische Archäologie* was established covering the archaeology of both early modern and more recent periods. Large-scale urban excavations have also taken place in Scandinavian cities including Lund (Sweden), Trondheim (Norway), and Copenhagen (Denmark) (Gaimster 2005) and in many cities in the Low Countries, notably Amsterdam (the Netherlands) and Antwerp (Belgium) (Bartels 1999). In France, post-medieval sites are excavated by the state archaeology service, but there is also a strong tradition of regional rural landscape and vernacular architecture studies. In Eastern Europe, post-medieval archaeology has developed from a strong tradition of ethnology and material culture studies as well as the large-scale urban excavations which have taken place since the collapse of Communism; David Gaimster has suggested that the European Council's funding of archaeology within medieval and post-medieval towns in the former eastern bloc has been a way of reemphasizing older shared traditions in the new Europe (Gaimster 2005). Italy has a dedicated research journal for the subject, *Archeologia Postmedievale* (founded in 1997); there has been extensive work on post-medieval ceramics and glass, reflecting the interest in the material culture of the Renaissance. Spain has seen only limited research on post-medieval archaeology, and in both Italy and Greece, there has been some recent work on post-medieval landscape surveys and vernacular architecture studies (Milanese 1997) (Fig. 4).

In Continental Europe, then, the major focus has been on the excavation and publication of early post-medieval urban sites and their rich material culture assemblages, with more limited work on rural landscapes and buildings. The archaeology of the household and domestic life has been a significant recent area, highlighting the potential for complex social and cultural analyses of material culture drawing on historical documents such as wills and probate inventories of household goods, as well as artistic depictions of early modern domestic interiors. One example of this is David Gaimster's study of the stoneware ceramic industries of the Rhineland, which developed in the fourteenth century and whose products were exported all over Northern Europe, Britain, and the European colonies in North America. Gaimster is able to bring together varied sources to show shifts in patterns of production,

Post-Medieval Archaeology (Europe), Fig. 4 The mercury distillation plant at Almadén, Castilla La Mancha, Ciudad Real, Spain. Mercury (from the mineral cinnabar) was essential to the expanding silver economy of the Spanish New World, and the mines at Almadén were a major state-owned concern. (© Marilyn Palmer)

trade, and consumption of this distinctive form of ceramic tableware, highlighting its role in new rituals of dining and the display of wealth and culture in middle-class European households (Gaimster 1997).

There remain significant challenges facing the development of post-medieval archaeology in Europe. As the majority of research is undertaken in the context of developer-funded projects, fostering a coordinated research framework is problematic, and the sheer scale and diversity of the material and built archaeology of the last 500 years create huge challenges in terms of management, publication, and archiving strategies. This is compounded by the natural tendency of each European country to publish in its own national language, making synthesis difficult to achieve. Only a few explicitly transnational studies have been undertaken for post-medieval object types, but these highlight the necessity to consider cross-European exchange of material culture in this period (Gaimster 1997; Veeckman 2002). British archaeologists, influenced by global historical archaeology, have pioneered the study of the eighteenth and nineteenth centuries and have recently highlighted the need for an archaeological approach to the material remains of twentieth-century and contemporary society. In contrast, there has been only very limited research on this later period on the Continent, largely through industrial archaeology and studies of buildings and landscapes, while archaeological excavations of twentieth-century material happen only occasionally, usually through the archaeological or forensic study of modern warfare and sites of atrocities. Many people still question the usefulness of archaeology for the study of a period with rich historical and visual records, but archaeologists have successfully demonstrated that the material remains of the recent past can provide unique and valuable insights into the dramatic social, economic, and political transformations which created, and continue to operate within, our present-day world.

Post-Processual Archaeology

Ian Hodder
Anthropology Department, Stanford University, Stanford, CA, USA

Introduction

Post-processual archaeology stemmed from critical debates about the nature of archaeology in the 1980s in Britain, Scandinavia, and the United States leading to much controversy in the 1980s and 1990s and often dividing the discipline into two camps, processual and post-processual. During the first decade of the twenty-first century, the debate has settled down, and many archaeologists attempt to integrate divergent perspectives within the discipline or pick and choose between them.

Definition

Post-processual archaeology began in the 1980s as a reaction to processual archaeology, and it came to be used as an umbrella term covering a wide range of approaches that engage with contemporary social theory and acknowledge the historical dimensions of knowledge production. These approaches have included discussions of power and ideology, feminism, shifts to and from the notion that material culture can be read as a text, phenomenology, accounts of agency, landscape, the body, memory, materiality, the links between archaeology and heritage, indigenous rights, and ethics.

Historical Background

In the early 1980s post-processual archaeology identified a series of oppositions that were not being debated within the discipline as a result of the approaches followed by processual archaeology. These were as follows:

System and structure: By focusing on variability in adaptive responses to environments as the main locus of cultural change, processual archaeology seemed to reject those large parts of anthropology and the social sciences and humanities which explored underlying structures (especially structures of power and structures of meaning).

Behavior and agency: Similarly by focusing on how humans responded to environments in predictable ways, and by focusing on material culture as an adaptive tool, processual archaeologists gave little import to the ways in which human agents actively used material culture to transform social worlds.

Anthropology and history: By espousing the view that archaeology was anthropological, comparative, and generalizing, processual archaeologists seemed to deny the validity of theories of history and the long tradition, at least in Europe, of linking archaeology with history.

Object and subject: By adopting a stringent view of science as following the hypothetico-deductive method, processual archaeologists used an outdated view of science that did not engage with a wide range of post-positivist philosophies and could not accommodate multiple conflicting perspectives.

In developing this critique, post-processual archaeologists had a number of influences. There were certainly some historical antecedents within archaeology, including the European tradition of linking archaeology with history seen, for example, in the work of Collingwood and Childe (Hodder and Hutson 2003). In North America some have suggested a precursor in the work of Walter Taylor, and Bruce Trigger and James Deetz were also influential. But the main influences were from outside archaeology.

In Britain and Europe these were from social and cultural anthropology (Edwin Ardener, Ernest Gellner, Mary Douglas, Clifford Geertz, Victor Turner, Marshall Sahlins) but mainly from Pierre Bourdieu and the Cambridge sociologist Anthony Giddens. In the United States important influences were from Marxism and critical theory, particularly in the context of historical archaeology, and from feminism and indigenous archaeology.

In the late 1970s and early 1980s in Cambridge, a group of graduate students and professors influenced by these ideas including Ian Hodder, Paul Lane, Danny Miller, Henrietta Moore, Mike Parker Pearson, and Chris Tilley organized seminars and a conference attended by Meg Conkey, Susan Kus, Marke Leone, and Alison Wylie. At the same time ethnoarchaeological research (e.g., by Hodder, Miller, and Moore) demonstrated ways in which the broad theoretical interests could be explored in relation to material culture.

In the resulting publications (e.g., Hodder 1982a, b; Leone 1982; Miller and Tilley 1984; Shanks and Tilley 1987a, b; Hodder and Hutson 2003) a number of themes were apparent. The first was that material culture is meaningfully constituted. This was a response to the ecological and adaptive emphases of processual archaeology, and it involved the analysis of structures of meaning and symbolism (see section "Key Issues" below). Another theme was that material culture is active not passive. This was a reaction to the functionalism and behaviorism of processual archaeology. Within both these themes, there was in the European debates a simultaneous rejection of structuralism and an embrace of the work of Bourdieu and his notion of habitus and of Giddens and his notion of structuration. These approaches seemed particularly appropriate for archaeology because they dealt with practice (how rules and structures are played out in the practices of daily life – including in the material objects and residues visible to archaeologists) and with the transformation of structures (how societies change through practice – again the approaches seemed relevant to a discipline dealing with long-term change). Various forms of post-structuralist critique were incorporated into publications and debates.

These changes in perspective within archaeological theory were not produced by a particular book, person, group, or movement. Rather they were made possible by a general change in archaeology that happened in response to wider shifts in related disciplines and in society at large. The main contributing influences were Marxism, structuralism and the post-structuralist critiques, feminist archaeology, postcolonial and indigenous archaeology, and post-positivist debates within the philosophy of science.

Marxism had long been an important component of theoretical debate in archaeology as a result of the work of Childe, but the specific impetus influencing the emergence of post-processual archaeology in Europe was the structural-Marxism of Godelier and Meillassoux and the archaeology of Rowlands and Friedman in which evolutionary change was dependent on specific historical interactions between the forces and relations of production. But it was the Marxist critique of theory and science that had most influence through the work of Mark Leone in the United States and particularly his work in the public archaeology project at Annapolis. As already noted, in addition to Marxist notions of structure, semiotics, structuralism, and post-structuralism (as in the work of Saussure, Lévi-Strauss, Derrida) all played their role in encouraging a more complex discussion in archaeology of the ways in which material culture is patterned and organized.

Early post-processual archaeology had an ambiguous relationship with feminist archaeology. As noted above, Moore, Conkey, and Wylie played significant early roles, but there was soon criticism of a lack of concern with feminist issues in, for example, the early writing of Shanks and Tilley (Engelstad 1991). It was not until 1990 that the first explicitly feminist archaeology emerged in volume form (Conkey and Gero 1990), and since then there have been many developments in feminist and gender archaeology dealing with issues close to those discussed in post-processual archaeology such as knowledge construction, context, ideology, reflexivity, identity, agency, and materiality (e.g., as seen in the work of Rosemary Joyce). Recent definitions of feminist archaeology overlap considerably with post-processual archaeology.

There is some debate about relationships between the growth of postcolonial and indigenous archaeologies and post-processual archaeology. There is a wide recognition in archaeology today that archaeology was historically aligned with nationalist, colonial, and imperial projects that separated many communities from their pasts and wrote the histories and prehistories of others in ways that reinforced dominant narratives (Trigger 1984, 2006). In its critique of processual archaeology's associations with particular forms of dominant discourse in science, post-processual archaeology was aligned to those groups claiming rights and identity to the material past. For example, the African Burial Ground project in New York has empowered contemporary descendants by giving them tangible, material evidence of their heritage and of the contributions and suffering of their once ignored, silenced, and disenfranchised ancestors (Blakey 1998). The passing of NAGPRA in the United States attempted to safeguard the interests of Native Americans with regard to their heritage. This has led to closer cooperation between archaeologists and Native Americans and to changes in archaeological method which involve Native American oral traditions and ritual observances within the scientific process (Watkins 2001; Wilcox 2009). The collaborative methods that have developed in North America as well as in Australia and other parts of the world parallel those developed in post-processual and reflexive archaeology (see below under section "Key Issues"). These indigenous and postcolonial archaeologies were not the product of post-processual archaeology, but they did create an environment in which post-processual theories could become salient.

Another important influence on the emergence of post-processual archaeology was debates within the philosophy of science that critiqued methods embraced by processual archaeology. Over many decades, philosophers of science have demonstrated the ways in which scientific knowledge production is situated historically. In cultural anthropology debates emerged about the ways in which ethnography involved complex interactions between observer and observed. But processual archaeology in the United States, perhaps because of its colonial context, rejected these post-positivist, interpretive, and reflexive moves. Initially some post-processual archaeologists took a strongly constructivist position although tempered with detailed empirical and quantitative research. Gradually through time various types of middle ground have been found between objectivist and constructivist positions (see section "Key Issues" below).

It is important to recognize the different contexts of post-processual archaeology in Europe (especially in Britain) and the United States. In Europe archaeology had always been linked to history, and so it responded less enthusiastically to processual archaeology and was consequently more ready to engage in its critique; this was especially true of Britain but also of Scandinavia. The major influences on post-processual archaeology in Britain were Bourdieu and Giddens and the post-structuralist debate. But in the United States, the major influences were feminism and Marxism, and the main initial impact was in historical archaeology. The archaeology of early societies and hunter-gatherers remained very tied to a universalizing approach. When cultural anthropology in the United States took a turn toward meaning, history, and reflexivity in the 1970s and 1980s, archaeologists shied away and took their own path, reinforcing a belief in behavioral universals and a restricted form of positivism. Cut off in this way from the intellectual trends that were influencing the growth of post-processual archaeology, the reaction in the United States was initially very strident. Even today, post-processual archaeology in the United States is usually seen as an accompaniment to a continuing processual archaeology, whereas in Britain the two approaches remain thought of as separate and opposing theoretical movements.

As a result of its complex and contested history, post-processual archaeology today can be defined in two rather different ways. For some it remains a term used to describe the more constructivist positions championed by Shanks and Tilley in 1987and more popular in Britain and Europe. For others, and this is the way the term is used here, it has a broader definition incorporating a wide range of perspectives including feminism, Marxism, heritage, and indigenous

archaeologies, as well as the variety of approaches to be discussed below. These approaches are held together loosely by their dialogue with contemporary social theory and by their acknowledgement of the historical dimensions of archaeological knowledge production.

Key Issues

As already noted, key early issues were that material culture is meaningfully and actively constituted. Semiotic, structuralist methods allowed archaeologists to explore the ways in which material culture has a meaning which goes beyond the physical properties and adaptive functions of an object and derives from the network of social strategies within which the object is embroiled. It is used by agents intentionally pursuing strategies and monitoring outcomes – even if the intentions are often not consciously understood and even if much material practice is routinized and produced by nondiscursive daily practices. The development of this perspective was heavily influenced by the "practice" and "structuration" theories developed by Bourdieu and Giddens where structure is the medium and the outcome of action. The emphasis on material culture being actively manipulated in order to legitimate or transform society was also found in Marxist-inspired archaeological studies in prehistoric Europe and in historical archaeology in the United States as well as in feminist archaeology.

If material culture is always meaningfully constituted, then perhaps it can be seen as a text that is read (Hodder 1986 in Hodder and Hutson 2003). This idea has several attractive aspects. It puts the emphasis on the reader – on the notion that meaning does not reside in the object itself but in the way that the reader makes sense of that object. The "reader" here is both the past social actor and the present archaeologist. The reading metaphor foregrounds the fact that different people will read the same data differently, a tendency for which there is much historical evidence. The text metaphor encourages us to focus on context – "with text." Rather than studying pottery and animal bones separate from each other and from their find context, the emphasis is placed on looking at pottery and animal bones and find circumstance in relation to each other. In each context there may be distinct or subtle changes of meaning. The text metaphor thus invites us to make use of the world of semiotics – the study of signs and the systems in which they are embedded.

But there are also difficulties with the text metaphor when applied to material culture. In particular the meanings of material things are rarely arbitrary; they are usually grounded in the material and practical experience of the world. For example, the symbolism of gold is tied to its rarity and the effort needed to obtain it, as well as to its durability. In the 1990s, post-processual archaeologists began to react against the textual metaphor (see Hodder et al. 1995) and to explore the ways in which material meanings were practically engaged, embodied, and experienced. Again the influences were from theories of practice, but they also derived from the phenomenology of Heidegger and Merleau-Ponty, very successfully taken up in archaeology by Chris Gosden, Julian Thomas, Chris Tilley, and Bjørnar Olsen.

Heidegger's aim, writing mainly in the first half of the twentieth century, was to get away from the long tradition in philosophy and Western thought in which reality is some kind of substance that is approached by detached theoretical reflection. He wanted to get away from a perspective in which things were seen as separate from humans and instead wanted to start in the very midst of practical daily activities, hammering in a nail, pouring water from a jug, and so on. Heidegger emphasized the practical everyday-ness of human existence by using the term "Dasein" (being there) instead of "human subject." He also used the hyphenated phrase "being-in-the-world" to point to the ways in which humans are situated in and inseparable from the world that is around them and into which they are thrown and dwell.

An important and highly influential use of phenomenology was Tilley's (1994) work on landscape. He argued that our own embodied experiences of landscapes and monuments today must reveal to us something of the experiences of the people who once inhabited those same places in the past. The approach, as also in the work of

Thomas and Barrett, has been very fruitful in encouraging archaeologists to explore how monuments and landscapes were made meaningful through their practical use. There are dangers since our responses as we walk through landscapes today are situated within our own beings-in-the-world. The approach asks archaeologists to consider how people moved round monuments and landscapes and how architecture and dwelling were embodied. Related issues deal with cultural and historical variation in how bodies, selves, and individuals are understood (Fowler 2004). For example, it is important to recognize that the atomized individual self is a Western product. Conceptions of individuals and body boundaries and the relationship between self and environment vary through time and space.

Another important aspect of the involvement of material culture in our experience of the world is in memory construction (Van Dyke and Alcock 2003). Archaeologists often observe evidence of the holding on to objects (heirlooms) over long periods of time. They have evidence of people reusing earlier settlements, burial locations, or ritual spaces. They have evidence of people digging up earlier remains and commemorating events or erasing monuments. In all these ways archaeologists have access to the ways in which people have remembered or forgotten their pasts. Such engagements with the archaeology of memory today have special salience in contexts in which contemporary societies use archaeology itself to deny histories or to foreground memories as part of post-conflict reconciliation and healing, whether in South Africa, Bosnia, or Argentina.

Another key recent theme has been the focus on materiality. This derives partly from the approaches identified above but also from engagement with a wide range of material culture studies within anthropology, including the work of Miller, Gell, and Ingold. The emphasis remains on the constitution of self and identity, but the focus shifts to how things act in the world. There is much recent work that explores how materials are construed in different social settings and historical contexts (Joyce 2005). Things, matter, fluids, life, and death – all these are construed differently in different historical contexts. The study of materiality explores these cultural relationships, and the biographies of objects are pursued through varying social contexts. Meskell (2004: 7) notes how in Egypt past and present "persons exist and are constituted by their material world: subjects and objects could be said to be mutually fashioning and dependent."

Running through all these discussions in post-processual archaeology about the ways in which things have meaning and play roles in social lives is the issue of agency. As noted above, the notion that material culture was actively used by people in pursuing discursive or nondiscursive strategies was a key early theme in post-processual archaeology, in reaction to the behaviorism of processual archaeology. The issue of agency has grown to be one of the central themes of post-processual debate, and indeed it has come to be an important bridging concept to other approaches in the discipline (Dobres and Robb 2000).

Agency is itself a complex process that needs to be broken down into its component parts. Different authors in archaeology refer to different aspects of agency. For example, Barrett (1994) mainly discusses the context for action – the fact that the actor has to be situated in relation to power/knowledge in order to have knowledge and resources to act. He discusses the mobilization of space and resources in prehistoric monuments in Britain in these terms. Many authors focus on the resources needed for a social person to act in the world.

A rather different approach argues that there is an intentionality to agency and that this intentionality cannot be reduced to the context for action. Of course, some intentions may be nondiscursive in the sense that actors may not be fully consciously aware of their motivations. Intentions need, therefore, to be interpreted. Archaeologists routinely make these interpretations. When claiming that a ditch is defensive or that a large wall around a settlement was built to provide prestige, intentions are imputed. The defensive nature of the ditch may be determined from its shape and size and position and from evidence of warfare and so on. The prestigious nature of the

wall may derive from its nondefensive nature (in terms of construction material or location or effectiveness). Another form of intentional social action is resistance to dominant groups. Many archaeologists have sought to demonstrate that subordinate groups use material culture to counteract dominant forms of discourse.

Any act can have intended and unintended consequences. Indeed another approach to agency takes the focus away from intentionality and focuses more closely on the impact of action on others and on the material world. In addition, the overall attention to the active components of material culture in phenomenology, memory, material culture, and materiality approaches has led to the notion that things too can have agency in the sense of having impact. Things can clearly act in the sense that a door closer closes the door after we have opened the door and walked through, as described by Bruno Latour. But they can also act in the sense that humans often give things powers, whether these powers be apotropaic, religious or spiritual, or involved in memory.

It is important to return to the question of method. Many positivist archaeologists adhere to some notion of objective data and hypothesis testing because they fear that the only alternative is a form of relativism in which "anything goes." In other words, they fear that if there is no possibility of objective testing, then anyone's statement about the past is equally as good as anyone else's. I know of no post-processual archaeologist who would take this line. There are various forms of relativism, and most archaeologists would accept that archaeological interpretation is and should be answerable to data. The question is really just a matter of "how."

Archaeology is not for the most part an experimental science in which variables can be held constant. Rather, it is, like geology, a historical science that works by fitting lots of different types of data together as best it can in order to make a coherent account (Hodder 1999). This emphasis on fitting rather than testing is at the heart of the hermeneutic or interpretive approach. Theories of interpretation place emphasis on making sense of the event in relation to what is going on around it while recognizing that generalizations have to be used. In the hermeneutic approach, it is recognized that the researcher comes to the data with much prior knowledge and prejudgments. The data are perceived within these prejudgments. The researcher then works by fitting all the data together so that the parts make up a coherent whole. The interpretation that works best both fits our general theories and prejudgments, and it makes most sense of more data than other interpretations. The process is not circular – that is, one does not just impose one's prejudgments on the data. The objects of study can cause us to change our ideas, but never in a way divorced from society and from perspective. There is thus a dialectical (dialogical) relationship between past and present and between object and subject. There is never a socially neutral moment in the scientific process, but equally, socially biased accounts can be transformed by interaction with objects of study.

Thus, like most archaeologists today, we have employed a broad battery of scientific techniques at Çatalhöyük (Hodder 1999). We are trying to do good science at Çatalhöyük and use a wide range of natural science techniques. We build arguments by using as many different crosscutting techniques as we can. But we are also aware of the ways in which our arguments are embedded in our own assumptions and starting points; we always have to be careful and vigilant about where our ideas are coming from. And we also have to be aware that our assumptions and starting points may exclude the interests of others who come to Çatalhöyük with different perspectives.

Early post-processual archaeology paid scant attention to method, and many post-processual archaeologists have continued to excavate and do research employing field methods developed in the heyday of processual archaeology. But in the late 1990s, a debate began to emerge about using field methods that were developed specifically for interpretive research. These reflexive methods (Hodder 1999) focus on encouraging multivocality, collaboration between different interest or stakeholder groups, and the documentation of the documentation process. By the latter

is meant the recording of the assumptions and methods involved in research so that future researchers can return to the data and understand their conditions of production. Provision of such secondary documentation opens up the archaeological process to later critique and reanalysis.

The embedding of archaeological science within the contemporary social process has been the most important aspect of post-processual archaeology. It has occurred at a time when archaeology has come to critique its dominant starting points and assumptions, for example, in response to feminism. During recent decades archaeology has also come to play an important role in postcolonial contexts as previously marginalized and dominated groups have used the past to regain rights to land and to legal existence. As noted above, post-processual archaeology is not the cause of these developments, but it has proved an effective ally for those seeking alternative pasts and for those wishing to break away from dominant narratives. The new collaborative methods employed in postcolonial, indigenous, and Native American archaeology are close to those used within this wider sphere.

Post-processual archaeology has played a central role in the emergence of a theoretical heritage discourse. The past is often contested, and the material past is often key to the assertion of rights to land and recognition, as already noted. More widely, material heritage has been involved in conflicts throughout the world from the destruction of the Bamiyan Buddhas to the destruction of the Mostar Bridge in Bosnia to the competing claims to the religious monuments in Jerusalem. In many countries, dealing with heritage has been central to post-conflict healing and reconciliation, as in South Africa after the end of apartheid. In all these cases the universal values of heritage (e.g., as defined by UNESCO) have to be weighed against local understandings and valences. The different interests of stakeholders have to be evaluated, and ethical positions debated. Increasingly the language of cultural rights and human rights in relation to heritage has been used. In all these ways, a post-processual approach has been active in this area (Smith 2004; Meskell 2009).

Current Debates/Future Directions

Many of the key issues identified above are currently debated within archaeology, particularly the relevance of phenomenology, different approaches to agency, discussions of landscape, the body, memory, materiality, the links between archaeology and heritage, indigenous rights, and ethics. But there are increasingly attempts made to bridge the divide between processual and post-processual archaeology. Several authors over the past two decades have argued for some blending of processual and post-processual approaches (e.g., Pauketat 2001). Today many people consider the processual/post-processual debate largely as historical, and they pick and choose between them pragmatically as seems appropriate.

As a result one can today say that it is difficult to place many forms of archaeology firmly on one side of the debate rather than the other. Thus, one might argue that on the whole, cognitive processual approaches in archaeology as well as behavioral archaeology, human behavioral ecology, and evolutionary and complexity theory approaches tend to derive their heritage mainly from processual archaeology. On the other hand, a post-processual heritage is dominant for materiality studies, phenomenology, postcolonial and indigenous archaeologies, and in critical heritage discourse. In practice each approach today borrows from or reacts to developments within other approaches. Links are recognized between complex systems and the historical contingencies described in much post-processual archaeology. Cognitive processual and phenomenological approaches seem equally engaged in problems of mind, perception, and materiality. Agency is a clear linking domain, central to materiality and postcolonial and indigenous archaeology as much as it is to complex systems, agent-based modeling, and evolutionary archaeology.

Many archaeologists are increasingly concerned with one of the key issues of our time – the relationships between culture and biology – and their relative importance. Many try to find some integration, arguing that culture and biology are both central to the project of being human. Such developments are

found, for example, in the dual inheritance approach within evolutionary archaeology but also within discussions of embodiment, materiality, and landscape. Both sides of the debate in archaeology increasingly aim to allow the play of biological processes within culture and society and within social change.

International Perspectives

As noted above, post-processual archaeology originated in Europe, especially in Britain and Scandinavia, and in the United States, especially in historical archaeology. It is clearly a Western discourse, tied to Western social theorists. On the other hand, its critique of the "one science" model and its recognition of the situated and historical dimensions of knowledge construction have meant that it has seemed relevant to archaeology in many parts of the world. A consideration of the wide global range of articles published in the Journal of Social Archaeology, or in Archaeologies, the journal of the World Archaeological Congress, demonstrates the wide global reach and diversity of interests encompassed by post-processual archaeology.

There are, however, regional variations in the debates regarding post-processual archaeology, and I have identified above the important differences between the development of the perspective in Europe (especially Britain) and in the United States. In the United States post-processual and processual archaeologies are often seen as accompanying each other, whereas in Britain post-processual archaeology is often seen as dominant and opposed to other approaches. Another regional difference occurs in Latin America and in parts of Spain where materialist, Marxist approaches have dominated theoretical debate for some time. Here aspects of post-processual archaeology have often been folded into an archaeology already socially and politically engaged. In other parts of the world too, post-processual perspectives have often become relevant in varied forms as part of postcolonial, indigenous, and political movements. The success of the World Archaeology Congress has demonstrated the need for broad theoretical debate on a global scale.

Post-Processualism, Development of

Ian Hodder
Anthropology Department, Stanford University, Stanford, CA, USA

Introduction

Post-processual archaeology initially developed in the 1980s in Britain, Scandinavia, and the United States as a response to processual archaeology and in particular in reaction to the lack of engagement of processual archaeology with contemporary social theory and the critique of positivism. After a period of controversy between processual and post-processual approaches in the 1980s and 1990s, many archaeologists have attempted to integrate aspects of both programs in their research. However, the epistemological differences remain and have led to the development of post-processual methods such as reflexive archaeology.

Definition

Post-processual archaeology began in the 1980s as a reaction to processual archaeology, and it came to be used as an umbrella term covering a wide range of approaches that engage with contemporary social theory and acknowledge the historical dimensions of knowledge production. These approaches have included discussions of power and ideology, feminism, shifts to and from the notion that material culture can be read as a text, discussions of phenomenology, accounts of agency, landscape, the body, memory, materiality, the links between archaeology and heritage, indigenous rights, and ethics.

Post-processual archaeology can be defined in two rather different ways. For some it was a term used to describe the more constructivist positions championed by Shanks and Tilley in 1987 and more popular in Britain and Europe. For others,

and this is the way the term is used here, it has a broader definition incorporating a wide range of perspectives including feminism, Marxism, heritage, and indigenous archaeologies as well as the variety of approaches to be discussed below. These approaches are held together loosely by their dialogue with contemporary social theory and by their acknowledgement of the historical development of archaeology as a scientific discipline.

Early Development

In the early 1980s, post-processual archaeologists identified a series of issues that were being debated in anthropology, the social sciences and humanities but that had been closed off from archaeological discussion by processual archaeology. These issues concerned structures of power and structures of meaning, the role of agency, the central importance of history, and epistemological questions concerning the relationships between subjects and objects. The main influences were from social theory, debates concerning Marxism and structuralism, feminism, indigenous archaeology, and postcolonial critiques of western archaeology (Hodder 1982a, b; 1986 [Hodder and Hutson 2003]; Leone 1982; Miller and Tilley 1984; Shanks and Tilley 1987a, b). For a description of the early development of and influences upon post-processual archaeology, see "Post-Processual Archaeology" entry in Preucel and Gnecco.

Post-processual archaeology developed differently in Europe (especially in Britain) and the United States. In Europe archaeology had always been linked to history and so it responded less enthusiastically to processual archaeology and was consequently more ready to engage in its critique; this was especially true of Britain but also of Scandinavia. The major influences on post-processual archaeology in Britain were Bourdieu and Giddens and the poststructuralist debate. But in the United States, the major influences were feminism and Marxism, and the main initial impact was in historical archaeology. The archaeology of early societies and hunter-gatherers remained very tied to a universalizing approach. When cultural anthropology in the United States took a turn toward meaning, history, and reflexivity in the 1970s and 1980s, archaeologists shied away and took their own path, reinforcing a belief in behavioral universals and a restricted form of positivism. Cutoff in this way from the intellectual trends that were influencing the growth of post-processual archaeology, the reaction in the United States was initially very strident. Even today, post-processual archaeology in the United States is usually seen as an accompaniment to a continuing processual archaeology, whereas in Britain the two approaches remain thought of as separate and opposing theoretical movements.

Post-processual archaeology has often developed differently in different parts of the world. Another regional difference occurs in Latin America and in parts of Spain where materialist, Marxist approaches have dominated theoretical debate for some time. Here aspects of post-processual archaeology have often been folded into an archaeology already socially and politically engaged. In other parts of the world too, post-processual perspectives have often become relevant in varied forms as part of postcolonial, indigenous, and political movements. The success of the World Archaeology Congress has demonstrated the need for broad theoretical debate on a global scale.

Developments in the 1990s

An early post-processual tenet was that material culture is meaningfully and actively constituted. Semiotic, structuralist methods allowed archaeologists to explore the ways in which material culture has a meaning which goes beyond the physical properties and adaptive functions of an object and derives from the network of social strategies within which the object is embroiled. Material culture is used by agents intentionally pursuing strategies and monitoring outcomes – even if the intentions are often not consciously

understood and even if much material practice is routinized and produced by nondiscursive daily practices. The development of this perspective was heavily influenced by the "practice" and "structuration" theories developed by Bourdieu and Giddens where structure is the medium and the outcome of action. The emphasis on material culture being actively manipulated in order to legitimate or transform society was also found in Marxist-inspired archaeological studies in prehistoric Europe and in historical archaeology in the United States as well as in feminist archaeology.

If material culture is always meaningfully constituted, then perhaps it can be seen as a text that is read (Hodder 1986 [Hodder and Hutson 2003]). This idea has several attractive aspects. It puts the emphasis on the reader – on the notion that meaning does not reside in the object itself, but in the way that the reader makes sense of that object. The "reader" here is both the past social actor and the present archaeologist. The reading metaphor foregrounds the fact that different people will read the same data differently, a tendency for which there is much historical evidence. The text metaphor encourages us to focus on context – "with text." Rather than studying pottery and animal bones separate from each other and from their find context, the emphasis is placed on looking at pottery, animal bones, and find circumstance in relation to each other. In each context there may be distinct or subtle changes of meaning. The text metaphor thus invites us to make use of the world of semiotics – the study of signs and the systems in which they are embedded.

The early development of post-processual archaeology had focused on the critique of processual archaeology. But in the 1990s, attempts began to be made to focus on the productive components of the theories being used and to offer a more coherent perspective in place of the diversity of views initially expressed. The emphasis on the interpretation of meaning allowed the label "interpretive archaeology" (Hodder et al. 1995). But the use of this term was short-lived as it quickly became apparent that there are difficulties with the text or reading metaphor when applied to material culture. In particular the meanings of material things are rarely arbitrary; they are usually grounded in the material and practical experience of the world. For example, the symbolism of gold is tied to its rarity and the effort needed to obtain it, as well as to its durability. In the 1990s, post-processual archaeologists began to react against the textual metaphor and to explore the ways in which material meanings were practically engaged, embodied, and experienced. Again the influences were from theories of practice, but they also derived from the phenomenology of Heidegger and Merleau-Ponty, very successfully taken up in archaeology by Chris Gosden, Julian Thomas, Chris Tilley, and Bjørnar Olsen.

An important and highly influential use of phenomenology was Tilley's (1994) work on landscape. He argued that our own embodied experiences of landscapes and monuments today must reveal to us something of the experiences of the people who once inhabited those same places in the past. The approach, as also in the work of Thomas and Barrett, has been very fruitful in encouraging archaeologists to explore how monuments and landscapes were made meaningful through their practical use. There are dangers since our responses as we walk through landscapes today are situated within our own beings-in-the-world. The approach asks archaeologists to consider how people moved round monuments and landscapes and how architecture and dwelling were embodied. Related issues deal with cultural and historical variation in how bodies, selves, and individuals are understood (Fowler 2004). For example, it is important to recognize that the atomized individual self is a western product. Conceptions of individuals and body boundaries and the relationship between self and environment vary through time and space.

Early post-processual archaeology paid scant attention to method, and many post-processual archaeologists continued to excavate and do research employing field methods developed in the heyday of processual archaeology. But in the late 1990s, a debate began to emerge about using field methods that were developed specifically for post-processual research. These reflexive methods (Hodder 1999) focus on encouraging multivocality, collaboration between different

interest and stakeholder groups, and the documentation of the documentation process. By the latter is meant, the recording of the assumptions and methods involved in research so that future researchers can return to the data and understand their conditions of production. Provision of such secondary documentation opens up the archaeological process to later critique and reanalysis.

The embedding of archaeological science within the contemporary social process has been the most important aspect of post-processual archaeology. It has occurred at a time when archaeology has come to critique its dominant starting points and assumptions, for example, in response to feminism. During recent decades, archaeology has also come to play an important role in postcolonial contexts as previously marginalized and dominated groups have used the past to regain rights to land and to legal existence. Post-processual archaeology is not the cause of these developments, but it has proved an effective ally for those seeking alternative pasts and for those wishing to break away from dominant narratives. The new collaborative methods (Colwell-Chanthaphonh and Ferguson 2004) employed in postcolonial, indigenous, and Native American archaeology are close to those advocated in reflexive archaeology.

Developments in the 2000s

Another important aspect of the involvement of material culture in our experience of the world is in memory construction (Van Dyke and Alcock 2003). Archaeologists often observe evidence of the holding on to objects (heirlooms) over long periods of time. They have evidence of people reusing earlier settlements, burial locations, or ritual spaces. They have evidence of people digging up earlier remains and commemorating events or erasing monuments. In all these ways, archaeologists have access to the ways in which people have remembered or forgotten their pasts. Such engagements with the archaeology of memory today have special salience in contexts in which contemporary societies use archaeology itself to deny histories or to foreground memories as part of post-conflict reconciliation and healing, whether in South Africa, Bosnia, or Argentina.

Another key recent theme has been the focus on materiality. This derives partly from the approaches identified above but also from engagement with a wide range of material culture studies within anthropology, including the work of Miller, Gell, and Ingold. The emphasis remains on the constitution of self and identity, but the focus shifts to how things act in the world. There is much recent work that explores how materials are construed in different social settings and historical contexts (Joyce 2005). Things, matter, fluids, life, death – all these are construed differently in different historical contexts. The study of materiality explores these cultural relationships, and the biographies of objects are pursued through varying social contexts. Meskell (2004: 7) notes how in Egypt past and present "persons exist and are constituted by their material world: subjects and objects could be said to be mutually fashioning and dependent."

Post-processual archaeology has played a central role in the emergence of a theoretical heritage discourse. The past is often contested, and the material past is often key to the assertion of rights to land and recognition. More widely, material heritage has been involved in conflicts throughout the world from the destruction of the Bamiyan Buddhas to the destruction of the Mostar Bridge in Bosnia to the competing claims to the religious monuments in Jerusalem. In many countries, dealing with heritage has been central to post-conflict healing and reconciliation, as in South Africa after the end of apartheid. In all these cases, the universal values of heritage (as defined, e.g., by UNESCO) have to be weighed against local understandings and valences. The different interests of stakeholders have to be evaluated and ethical positions debated. Increasingly the language of cultural rights and human rights in relation to heritage has been used. In all these ways, a post-processual approach has been active in this area (L-J Smith 2004; Meskell 2009).

Increasingly attempts are being made to bridge the divide between processual and post-processual archaeology. Certainly different traditions of research have been sustained. Thus one

might argue that on the whole cognitive processual approaches in archaeology as well as behavioral archaeology, human behavioral ecology, and evolutionary and complexity theory approaches tend to derive their heritage mainly from processual archaeology. On the other hand, a post-processual heritage is dominant for materiality studies, phenomenology, and postcolonial and indigenous archaeologies and in critical heritage discourse. Indeed it is possible to argue that the genealogies of current approaches can be traced to three general perspectives: culture history, processual, and post-processual. Despite some blending and slippage to be discussed below, in origin each theoretical position seems to see itself as largely in one or other of these camps. By culture history I mean approaches in archaeology that are concerned with the descent and affiliation of ceramic and other types through time. The differences between processual and post-processual archaeology have increasingly become aligned with the wider divisions within contemporary intellectual life between universal rationalism and positivism on the one hand and contextual and critical reflexivity on the other (Fig. 1).

Many approaches in archaeology are less clearly assignable to one approach or the other. For example, while feminist, Marxist, and indigenous archaeologies can be claimed to be part of post-processual archaeology (Hodder and Hutson 2003), others argue for independent positions for these perspectives (Moss 2005). However one cuts the cake, most archaeologists are aware of deep differences between approaches in which actors act rationally according to universal principles (optimizing or minimizing) and those in which activity is meaningfully and socially produced in complex historical and cultural contexts; and they equate the former with positivism and hypothesis testing and the latter with some form of critical reflexive science.

These different perspectives and their multiple subdivisions are linked to different sites of the production of archaeological knowledge. There are clear underlying differences between the types of interests and questions of those using general evolutionary approaches and those concerned with history and agency. Evolutionary and human behavioral ecology tend to focus on less complex societies including hunter-gatherers and fishers. Issues of power and agency are most easily dealt with in more complex and historical societies. Theories of memory construction and cultural rights to the past most readily engage materiality and heritage studies. Phenomenological approaches seem easiest to apply in prehistoric landscape studies. More generally, colonial archaeologies as in the United States seem most wedded to universalizing behavioral approaches, while postcolonial contexts, as in the rise of indigenous archaeology in the United States and elsewhere, readily lead to critical, historicizing, and collaborative perspectives.

Despite these differences, several authors over the past two decades have argued for some

Post-Processualism, Development of, Fig. 1 One possible view of the historical relationships between some of the current theoretical approaches in archaeology

blending of processual and post-processual approaches (e.g., Hegmon 2003; Pauketat 2001; Wylie 1989) though not without critique (Moss 2005). Today many archaeologists consider the processual/post-processual debate largely as historical, and they pick and choose between them pragmatically as seems appropriate. Renfrew (1994) has talked of reaching an accommodation between processual and post-processual archaeology in cognitive processual archaeology. Kohler (2012) suggests that current approaches to complex systems incorporate critiques of a simple positivism, and he refers to Bintliff's (2008) argument that complexity theory integrates culture historical, processual, and post-processual perspectives. Schiffer (2010: 154) says that in the 1990s, he and others "sought to revitalize the behavioral program by adopting some post-processual research questions." This task was approached by applying the behavioral approach to ritual and religion, symbolic behavior, social power, and landscapes. For example, Walker (1995) examined the material and behavioral practices of ritual rather than the belief systems involved. The life histories of ritual artifacts were seen as leading to particular modes of deposition.

In practice today, each approach borrows from or reacts to developments within other approaches. Links are recognized between complex systems and the historical contingencies described in much post-processual archaeology. Cognitive processual and phenomenological approaches seem equally engaged in problems of mind, perception, and materiality. Agency is a clear linking domain, central to materiality and postcolonial and indigenous archaeology as much as it is to complex systems, agent-based modeling, and evolutionary archaeology.

Many archaeologists are increasingly concerned with one of the key issues of our time – the relationships between culture and biology and their relative importance. Many try to find some integration, arguing that culture and biology are both central to the project of being human. Such developments are found, for example, in the dual inheritance approach within evolutionary archaeology but also within discussions of embodiment, materiality, and landscape. Both sides of the debate in archaeology increasingly aim to allow the play of biological processes within culture and society and within social change.

Remaining Epistemological Differences

Despite all the evidence of increased interaction and accommodation between those approaches with processual and post-processual affinities, an apparent epistemological and methodological divide remains. Most of those in the United States who remain uncomfortable with the social theoretical questions posed in various forms of post-processual archaeology do so because they believe that post-processual archaeology threatens science in some way. Thus, Schiffer (2010, 155) argues that many behavioral archaeologists have adopted the research foci of post-processual archaeology and that they will place them "on a scientific foundation." Renfrew's concern in developing a cognitive processual archaeology resulted from similar fears.

What, then, are these key epistemological differences? Most processual archaeologists espouse some version of positivism and adhere to some notion of objective data and hypothesis testing because they fear that the only alternative is a form of relativism in which "anything goes." In other words, they fear that if there is no possibility of objective testing, then anyone's statement about the past is equally as good as anyone else's. I know of no post-processual archaeologist who would take this "anything goes" line. There are various forms of relativism, and most archaeologists would accept that archaeological interpretation is and should be answerable to data. The question is really just a matter of "how."

Archaeology is not for the most part an experimental science in which variables can be held constant. Rather, it is, like geology, an historical science that works by fitting lots of different types of data together as best it can in order to make a coherent account (Hodder 1999). This emphasis on fitting rather than testing is at the heart of the hermeneutic or interpretive approach. Theories of interpretation place emphasis on making sense of the event in relation to what is going

on around it while recognizing that generalizations have to be used. In the hermeneutic approach, it is recognized that the researcher comes to the data with much prior knowledge and pre-understandings. The data are perceived within these pre-understandings. The researcher then works by fitting all the data together so that the parts make up a coherent whole. The interpretation that works best both fits our general theories and pre-understandings, and it makes most sense of more data than other interpretations. The process is not circular – i.e., one does not just impose one's pre-understandings on the data. The objects of study can cause us to change our ideas but never in a way divorced from society and from perspective. There is thus a dialectical (dialogical) relationship between past and present and between object and subject. There is never a socially neutral moment in the scientific process, but equally, socially biased accounts can be transformed by interaction with objects of study.

But is there a real difference in practice between the processual positivist approach and the post-processual critical, dialectic, or hermeneutic approach? Is there any real difference between hypothesis testing and the hermeneutic spiral? The positivist view of science is that hypotheses are tested against data and they are confirmed or contradicted by the data, leading to new hypotheses which are themselves open to scrutiny and testing in the same way. In the hermeneutic spiral, the archaeologist starts with pre-understandings, evaluates the data to see how much fit there is, recognizes that the data do not all fit, and accommodates understandings, leading to new evaluations of fit. In practice these two approaches seem identical, except that the terms fit and test, understanding, and hypothesis are different.

So is all the fuss about nothing? Is the difference between the two approaches really about the choice of words and about how science is described? Both approaches claim to be scientific, so are the differences just about how science is understood? In many ways the differences have been overdrawn in the archaeological debate over recent decades. In many discussions the use of analytical or natural science techniques has been associated with positivist science, even though many historians of science would today argue against a positivist account of science. Post-processual archaeologists have used scientific techniques without adhering to a positivist framework.

But apparent differences remain. Within a positivist hypothesis testing framework, the main emphasis is placed on the role of objective and independent data. Wherever the hypothesis comes from, the data will allow the selection of the hypothesis that best fits. But within a hermeneutic framework, the pre-understandings play a significant role. They determine how the data are seen in the first place. However, much fitting/testing is carried out; the pre-understandings exert an influence. A clear example is the way in which Neolithic polished stone axes were for centuries thought to be thunder bolts. Within such a pre-understanding, it was not possible to develop hypotheses about how effective the "thunderbolt" was in woodworking. Such a hypothesis could only be entertained when the pre-understanding shifted and the "thunderbolt" was seen as an axe. Many pre-understandings derive from specific historical contexts of the production of knowledge. It is necessary for these pre-understandings to be critiqued at the same time as fitted to/tested against data. As a result differences remain between the social engagement of post-processual archaeology and the trust in a distanced objective science in processual archaeology.

Conclusion

Like most archaeologists today, we have employed a broad battery of scientific techniques at Çatalhöyük (Hodder 1999). We are trying to do good science at Çatalhöyük and use a wide range of natural science techniques. We build arguments by using as many different cross-cutting techniques as we can. But we are also aware of the ways in which our arguments are embedded in our

own assumptions and starting points; we always have to be careful and vigilant about where our ideas are coming from. And we also have to be aware that our assumptions and starting points may exclude the interests of others who come to Çatalhöyük with different perspectives.

So, in the end, despite the attempt by many to argue that processual and post-processual archaeology are developing close ties and common research questions, there remain important differences in terms of the role of the archaeologist in society. Although there are exceptions, on the whole the approaches identified as processual, remain committed to the analytical process as the sole sphere of a scientific process. On the other hand, those approaches identified as post-processual tend to be more ready to describe the scientific process as both analytical and at the same time responsive to critical reflection.

Post-Second Temple Judaism Archaeology

Steven H. Werlin
Independent Researcher, New Haven, CT, USA

Introduction

Post-Second Temple Archaeology emerged as a result of early twentieth-century discoveries. Prior to that time, the scholarly consensus followed the traditional view that with the destruction of Jerusalem in 70 CE, the Jewish people were scattered among the nations and ceased to be an archaeologically relevant group in ancient Palestine. Early archaeological surveys by European scholars brought to light a wealth of evidence suggesting that Jews continued to thrive as cohesive communities, especially in the northern part of the country, that is, Galilee and the Golan Heights. Survey evidence appeared in the form of synagogue structures, architectural fragments decorated with Jewish motifs, and inscriptions in Hebrew, Aramaic, and Greek. In addition, important discoveries at sites such as Beth She'arim, Beth Alpha, Hammath Tiberias, and Dura-Europos in Syria paved the way for a new field of Jewish Archaeology (Fine 2005). Often considered a subfield of Roman and Byzantine Archaeology, Art History, or Jewish Studies, the archaeology of post-70 Judaism typically has been approached either through the lens of other cultures (Roman and Byzantine Christian) or within the framework of Jewish history.

Definition

The Second Temple period effectively ended with the destruction of Jerusalem in 70 CE. Although a few post-70 events, such as the siege of Masada, are treated as part of Second Temple Archaeology, the capture of Judaism's capital and holy city, as well as the destruction of the Jewish Temple, brought the First Jewish Revolt against the Romans (66–70 CE) to a close. The end of political autonomy for the Jews and the loss of Judaism's central religious institution mark a watershed in Jewish history that according to the traditional view inaugurated the Rabbinic period. As a result of discoveries relating to the Second Jewish or Bar-Kokhba Revolt (132–135 CE), some archaeologists and historians have reassessed this periodization, suggesting that 135 CE was a greater turning point in the history of the Jewish people.

The use of the term "Rabbinic period" presupposes the rise and ultimate hegemony of the rabbinic class in Jewish society. Rabbis are commonly understood as religious scholars and teachers. The theological precepts of the ancient rabbis are known through their extensive corpus of religious literature composed, edited, and redacted between the end of the Second Temple period and the medieval period. The earliest post-70 rabbis are known as *Tannaim*, and so their works, written primarily in Hebrew, are known as "Tannaitic" literature. The most important Tannaitic work is the Mishnah, edited in the early third century. The second and third centuries are often referred to therefore as the Mishnaic or Tannaitic period by historians, rabbinicists, and archaeologists. The successors of the *Tannaim* are referred to as the *Amoraim*, and their works, written primarily in Aramaic, are known as "Amoraic" literature. The most important Amoraic work is the Gemara, a detailed commentary on the Mishnah. These two works together comprise the Talmud. The fourth and sixth centuries are occasionally referred to as the Amoraic period. More often, the entirety of this period between the second and sixth centuries is termed the "Talmudic period."

The Rabbinic or Talmudic period corresponds with the nebulous term Late Antiquity. In Palestine, these centuries include the Late Roman period (mid-second to mid-fourth centuries) and the Byzantine period (mid-fourth to early seventh centuries). Some Late Ancient studies of Jews in Palestine include the beginning of the Early Islamic period as well. The Early Islamic period in Palestine is sometimes divided into the

Umayyad period (mid-seventh to mid-eighth centuries) and the Abbasid period (mid-eighth to mid-ninth centuries).

The geographic scope of Judaism in the post-70 period is fairly broad. The homeland of the Jewish people was ancient Palestine, alternatively known as the Land of Israel or Judea, depending on the source. By the late Hellenistic period (second century BCE), Jews had begun to emigrate to lands all over the Mediterranean and Near East. Writing in the years following the First Jewish Revolt, Flavius Josephus indicates that Jews inhabited virtually every major city of the Roman Empire. It is traditionally assumed that the failure of the First Jewish Revolt exacerbated the dispersion of Jews beyond Palestine, although some now believe that the failure of the Bar-Kokhba Revolt 65 years later played a greater role. Archaeologically, Diaspora Judaism is best attested by a dozen or so synagogues and burials throughout the Mediterranean Basin (see below), with very little material remains from the large communities in Babylonia known from the historical sources.

Historical Background

In 70 CE, the Roman army, under the command of Flavius Titus, besieged and ultimately captured Jerusalem, officially ending the First Jewish Revolt. The city's Temple, which served as the religious and political epicenter of Judaism, was destroyed in the process. To suppress further flares of insurrection, the Tenth Roman Legion (Fretensis) encamped on the ruins of the city, expelling all inhabitants.

This loss was detrimental to Jewish society. Not only did Jerusalem serve as the political and cultural capital, but, as the home of the only Jewish Temple, it was the sole locus of worship, that is, sacrifice, to the God of Israel. Scholars traditionally have maintained that the Jerusalem priesthood, which enjoyed religious and political hegemony in Judaism, ceased to function in its official capacity, since sacrifices could no longer be made. Recent scholarship though has considered a possible reemergence or continuation of the priesthood in a more authoritative capacity beyond 70 CE than has been assumed (see below).

As a consequence of the revolt, the Romans established the province of Judea, thereby introducing permanently stationed troops into the country and direct administration by the Roman military. The end of Jewish political autonomy in part led to a second revolt, led by Simeon bar Kosiba, known by the messianic title Bar-Kokhba (or "Son of a Star") in 132–135 CE The literary sources for the Bar-Kokhba Revolt are very meager, especially compared to the detailed accounts of the First Jewish Revolt. Most information has been gleaned from numismatic evidence and correspondence documents uncovered in the rebels' refuge caves in the Judean Desert (Yadin 1971). Some scholars believe that the Jewish rebels succeeded in capturing Jerusalem during the revolt, a presumed goal, although the evidence is not conclusive. In any case, the revolt was finally suppressed in 135 or 136. As punishment, Hadrian forbade Jews to inhabit the region surrounding Jerusalem, refounding the city as the Greco-Roman polis of Aelia Capitolina. In addition, the province was renamed Palaestina following the term used by the Greek historian Herodotus, based on the biblical Philistines who lived along the southern coast and western lowlands of the country during the Iron Age.

Following the two failed revolts, the majority of the Jewish population migrated northward to Galilee. With the loss of the Jerusalem Temple, Judaism faced a theological dilemma of how and where to worship. By most accounts, Jewish religious life became increasingly centered around the synagogue, or "meeting house," for communal worship (Levine 2005). While the primary means of Jewish worship during the Second Temple period was sacrifice in the Jerusalem Temple, personal and communal liturgy and Torah reading became increasingly important and standardized in the post-70 era. It was during this time that rabbinic literature flourished as the written records of debates surrounding the proper means (*halakhah*) of observing each biblical

commandment (*mitzvah*). Over the following centuries, these works were edited and embellished with commentary and tangential anecdotes (*haggadah*), thus providing perspectives on Jewish life. Unfortunately, the highly redacted rabbinic documents amount to a tangled web of details from different lands over the course of a half-millennium, and so they are highly problematic sources for historically reliable information.

The difficulty of the historical sources muddles our picture of Jewish society somewhat during Late Antiquity. One area of perennial debate among scholars is the extent and definition of the "rabbis." The most traditional view is that the rabbis comprised a class of religious scholars and sages who effectively led Jewish society. Critical views, however, contest that this group was marginal in reality and that they merely portray themselves as authoritative in their literary works (Schwartz 2001; Levine 2011). Similarly, recent studies have questioned what role Jewish priests may have played in this period, especially since archaeological discoveries point to priestly and Temple-related concerns in Late Ancient synagogues (see below). Rabbinic literature further attests to the existence of a Jewish Patriarch, seated in the urban centers of Lower Galilee until the early fifth century. While the role of this figure has been debated, it is generally believed that this official facilitated interaction between the Roman government and Jewish populace with a tenuous sanction by prominent rabbis.

Another recurrent theme in the study of post-70 Judaism is interaction with non-Jews. The proliferation of Greco-Roman culture in Palestine from the first century onward was conceived by many ancient authors as a challenge to the traditional observance of Judaism. However, as archaeological discoveries and critical readings of the rabbinic texts have shown, Jews found themselves increasingly comfortable with displays of figural art, Roman civic institutions, and even the worship of polytheistic deities by non-Jews within their cities. The rise of Christendom in the fourth century posed a new challenge by a faith that claimed the same biblical tradition as the Jews. Between the fourth and seventh centuries, Palestine underwent a demographic shift that brought the majority of inhabitants under a single religious identity. The heretofore neglected province was thrust onto the international stage, as royal endowments catalyzed the construction of churches and monasteries, as well as an influx of pilgrims to the "Holy Land." Despite the theological and social challenge of Christianity, Jews apparently flourished amid the resulting economic boom, building the most elaborate synagogues the country had ever seen or would again until the modern era.

Palestine's prosperity flagged with the Byzantine wars against the Sassanian Persians in the early seventh century. The weakened political and economic circumstances set the stage for the relative ease of the Islamic Conquest of Palestine (636–640). Evidence from several synagogues in both Galilee and the southern part of the country suggests that Jews continued to live in Palestine much as they had under Byzantine Christian rule. While there is little evidence to support the notion that Jews faired any worse under the Umayyad or Abbasid caliphates, the archaeological evidence suggests that the boom of synagogue construction seen in the Byzantine period had come to an end.

Key Issues/Current Debates

There can be little doubt that synagogue studies dominate the archaeology of post-70 Judaism. Between 60 and 70 individual synagogue buildings dating to the Late Roman and Byzantine periods have been identified in Palestine and the Diaspora. Additional evidence in the form of decorated architectural fragments and inscriptions removed from context attests to dozens, if not hundreds, more synagogues that existed in antiquity (Milson 2007). (Several Samaritan synagogues have also been uncovered, though despite their similarity in form to Jewish synagogues, they remain part of a distinct religious tradition).

Considerable debate has erupted over the past few decades concerning the dates of the earliest post-70 synagogues. Rabbinic literature attests to the existence of the synagogue as an institution during the second–third centuries, but there is

very little archaeological evidence of synagogues prior to the fourth century (Gal 1995; Ma'oz 1999; Magness 2001; Milson 2007: 22–30). The apparent gap in the archaeological record of the second–third-century synagogue is most likely due to the nature of the building during the Late Roman period. That is to say, synagogues probably were modest and unimposing structures, in the style known from Second Temple period sites such as Masada and Gamla. As a result, they are difficult to find in the archaeological record. The only example with an uncontested mid-third-century date comes from Dura-Europos, where a synagogue was modified from a private home rather than a purpose-built monumental structure and preserved due to an unusual set of circumstances (see below). In any case, the height of monumental synagogue building in Palestine appears to begin in the fourth century and continue into the sixth century, although many synagogues remained in use into the seventh century or later (Milson 2007).

Some synagogues were built as Roman basilicas, with an internal colonnade and triportal façade on the Jerusalem-oriented wall. This type of synagogue is sometimes referred to as the "Galilean" type, after its primary region of occurrence. Important examples of Galilean-type synagogues include the sites of Capernaum, Bar'am, Meiron, Arbel, Gush Halav, Chorazin, and Nabratein (Kohl and Watzinger 1916; Corbo et al. 1972–2007; Meyers et al. 1981; Meyers et al. 1990; Yeivin 2000; Meyers and Meyers 2009). These synagogues were typically paved with flagstones and decorated with stone relief work. Alternatively, during this same period, Jews constructed synagogues that resembled church architecture more closely, often laid out as a colonnaded hall with an apse on the Jerusalem-oriented wall and preceded by a narthex and atrium, most of which was paved in decorative mosaics. Important examples of this type of synagogue include Beth Alpha in Lower Galilee and Na'aran in the lower Jordan Valley (Sukenik 1932).

Most synagogues, however, did not follow a standard layout, a point which has been underscored through discoveries and studies over the past few decades. Despite early attempts by archaeologists to create a synagogue typology and identify standardized architecture (Avi-Yonah 1978), less regularly planned synagogues such as at Hammath Tiberias, Khirbet Shema', En-Gedi, Sepphoris, and elsewhere have demonstrated the diversity of synagogue architecture (Dothan 1983–2000; Meyers et al. 1976; Barag 1993; Weiss 2005). These synagogues included apses and niches, courtyards and forecourts, or mosaics and relief works as the local communities and architects saw fit. In this way, the overall picture differs somewhat from the more standardized church architecture of Byzantine Palestine, perhaps a reflection of the decentralization of post-70 Judaism.

The synagogue discoveries of the early twentieth century uncovered an unexpected wealth of Jewish art. The earliest finds by the German survey team of Heinrich Kohl and Carl Watzinger in 1905–1906 showed that Jews decorated their buildings with stone relief using some of the same motifs and styles as Classical architecture (Kohl and Watzinger 1916). Likewise, the discoveries at Dura-Europos, Na'aran, and Beth Alpha demonstrated the breadth of Jewish representational art in the form of wall paintings and mosaic pavements (Sukenik 1932; Kraeling 1956). Again, these works utilized Greco-Roman and Byzantine motifs and styles, including animal representation, the Zodiac cycle, and even depictions of the sun god, Helios. Alongside non-Jewish or religiously neutral themes were biblical scenes and motifs referencing Jewish liturgical practices and sacred occasions, such as the ram's horn (*shofar*) used in the celebration of the New Year (Rosh Hashanah), the bound branches and citron (*lulav* and *etrog*) used during the Festival of Tabernacles (Sukkot), and the Torah Shrine façade depicting the elaborately decorated closet in which the synagogue's biblical scrolls were stored. (Alternatively, some have interpreted the Torah Shrine façade as a representation of the Jerusalem Temple, while others have argued that it is a symbolic reference to both the Torah and the Temple at the same time, Hachlili 1988: 272–80).

The most important Jewish motif used during this period was the seven-branched candelabrum

or *menorah*. Based on the decorative furniture described in the Bible and later used in the Jerusalem Temple, the *menorah* became a symbol of Judaism in Late Antiquity. Although a few depictions of the *menorah* appear as early as the late Second Temple period, the use of the motif as an ethnic identifier and Jewish symbol became widespread in the fourth century, coinciding with the rise of the cross as the identifying mark of Christianity (Hachlili 2001).

Among the most important testaments to the wealth of synagogue art comes from Syria, at the site of Dura-Europos on the Euphrates River (Kraeling 1956). The building itself is rather unremarkable, but the interior walls were richly decorated with wall paintings depicting a variety of biblical scenes. The walls in the Dura-Europos synagogue were preserved because the building was filled with earth as a defense measure during the city's siege by the Persians in the mid-third century. The scenes depict figures and scenes from the Hebrew Bible, melding Late Roman and Persian styles.

Beyond the synagogue, Jewish art found an important outlet in funerary contexts. The most notable Jewish cemetery is the necropolis of Beth She'arim in Galilee, where Jewish burials of the third–sixth centuries were identified on the basis of inscriptions in Hebrew, Aramaic, and Greek (Mazar et al. 1973–76). Relief carvings on sarcophagi and tomb walls include Jewish symbols, such as the *menorah*, as well as animals, human faces, and even a scene from Greco-Roman mythology. The inscriptions identify several of the interred as rabbis and indicate that some came from the Diaspora.

These archaeological discoveries of Jewish art came as a surprise to scholars of rabbinics and Jewish history in the early and mid-twentieth century. The rabbinic treatment of the Second Commandment (Ex. 20: 4–6) suggests that Jews adhered to a strict forbiddance of figural imagery, that is, representations of living creatures, especially the human form (Fine 2005; Levine 2011). Depictions of animals, biblical scenes, and Greco-Roman mythological beings would seem to contradict the traditional view of ancient Judaism. Archaeologists and historians have grappled with this dilemma for a century. Among the most thorough studies was that of E. R. Goodenough. Based in part on the richly decorated walls of the Dura-Europos synagogue, Goodenough proposed that a form of "Hellenistic Judaism," running counter to rabbinic traditions, was responsible for such lavish decoration (Goodenough 1953–65).

Although few scholars accepted Goodenough's overall thesis, the notion that alternative forms of Judaism existed in the ancient world was intriguing. The representations of liturgical paraphernalia – such as the *lulav*, *etrog*, and *shofar* (see above) – led some to identify deliberate references to the Jerusalem Temple. Archaeological evidence has been cited to demonstrate that the Temple's former priesthood, once the dominant religious group in Jewish society, became influential in the synagogue during Late Antiquity. The priestly connection is supported by several inscriptions citing donations made by priests and two plaques listing the priestly courses (*mishmarot*) known from the biblical book of Chronicles.

On the other hand, there is evidence that rabbinic attitudes toward figural imagery adjusted to accommodate the realities of their world. Scholars have pointed to rabbinic expositions of biblical texts that incorporate the meanings expressed in the artistic traditions of the synagogue. Other studies have interpreted artistic programs – that is, individual panels or units in a building's art that are "read" as a unified message – in synagogue art through the lens of rabbinic literature. The most detailed example of this method comes from the final report of the Sepphoris synagogue (Weiss 2005). These studies favor a maximalist position regarding rabbinic participation in the synagogue. More telling, however, is the Rehov synagogue, where an extended inscription – the longest ever found in a synagogue – quotes a passage known from rabbinic literature. The passage concerns the agricultural regulations pertaining to tithing and the Jewish seven-year sabbatical cycle.

Over the last decade, an important challenge to the traditional history of Jewish society in the post-70 era was proposed by Seth Schwartz. Schwartz suggested that Judaism all but collapsed

in the wake of the failure of the Bar-Kokhba Revolt (132–135 CE), and Jewish society succumbed to the Greco-Roman cultural matrix, abandoning the religious practices developed over the course of the Second Temple period. According to Schwartz, Judaism reemerged in the mid-fourth century, as Christianity became dominant in Palestine and forced a more exclusive form of worship than its polytheistic predecessor (Schwartz 2001).

As many critics have pointed out, the wealth of rabbinic literature from the second to fourth century poses a particular difficulty for Schwartz's thesis. From the perspective of archaeology, Schwartz's case is supported by the redating of many synagogues, especially the Galilean-type buildings, once thought to be Late Roman, but now generally considered products of the fourth century and later. In addition, Schwartz points to figural imagery on city-coins and other finds from Sepphoris and Tiberias in Lower Galilee to suggest that these were typical Greco-Roman cities in the Late Roman period, inhabited by Jews but indistinguishable from their non-Jewish neighbors and suffused with "pagan" culture. By the mid-fourth century, however, the Christianization of the Roman world marginalized and excluded Jews, forcing them back into the ancestral religion and culture that had been preserved tenuously by a small group of rabbis.

Schwartz's overall thesis is not generally accepted, but like Goodenough's study, it has posed an important challenge to the field, forcing scholars to rethink approaches to the archaeological evidence. For example, does the general absence in the archaeological record of the second- and third-century synagogue in Palestine indicate that Jews did not build synagogues – or even practice Judaism – at that time? Or does it suggest that the synagogue took a wholly different form than archaeologists and historians expect? Or, conversely, are there other processes – such as preservation or the reuse of sites and building materials – at play that might obscure the remains? As a result of Schwartz's study, a reconsideration of how the material evidence should be used in historical reconstruction alongside literary sources has characterized much of the research in the past decade.

Archaeology has made an especially significant contribution to the study of Diaspora Judaism in the post-70 era. A dozen or so ancient synagogues are known from the Roman and Byzantine world outside of Palestine, including examples from Italy, North Africa, Greece, Albania, Bulgaria, Turkey, and Syria. In addition to the third-century building from Dura-Europos (see above), excavations in the synagogue of Ostia near Rome have shown that the building was used for Jewish liturgy from at least the fourth century onward, and perhaps earlier. At Sardis in Turkey, a great hall attests to the largest synagogue known from the ancient world. Interestingly, the building originally was part of the civic center but apparently was acquired by the Jewish community and converted into a synagogue in Late Antiquity, suggesting that Jewish communities enjoyed a high socioeconomic status as late as the sixth century, despite literary sources that attest to occasional persecution.

International Perspectives

As with most subfields in the study of ancient Palestine, the archaeology of post-70 Judaism is fraught with controversies over the cultural heritage. Many of the relevant sites are located in the contested territories of the West Bank and the Golan Heights. As a result, questions surrounding the ownership of sites and finds have played an occasional role in the negotiations between the State of Israel and the Palestinian National Authority and the politics of the region.

Future Directions

Recent and new excavations in Late Ancient Jewish cities and villages over the past decade or two continue to fuel the study of post-70 Judaism. As the results of excavations at Sepphoris and Khirbet Qana during the 1990s and early 2000s emerge, evidence of city and village life for Jews during the Late Roman period will come to light, thereby addressing in part the challenge of Seth Schwartz's thesis (see above). In addition, new

synagogue excavations have begun over the past few years at Khirbet Wadi el-Hammam and Huqoq, both in Galilee. Both have incorporated into their project goals a study of the associated village in addition to the site's synagogue. The results will provide fresh perspectives on Jewish life beyond monumental and religious architecture.

Potato: Origins and Development

Tim Denham
Archaeological Science Programs, School of Archaeology and Anthropology, ANU College of Arts and Social Sciences, The Australian National University, Canberra, ACT, Australia

Basic Species Information

The potato (*Solanum tuberosum* L.) is one of the most significant food crops cultivated globally. From initial domestication in the central Andean region, potatoes have spread across the world to become the dominant tuberous crop in temperate climates. In contrast to many root crops, several major volumes have been published on the history of potato domestication and cultivation (e.g., Salaman 1949; Hawkes 1990).

The potato (*Solanum tuberosum*) is a flowering plant of the Solanaceae family, which includes several other domesticated plants such as tomato (*Solanum lycopersicum*), aubergine (*Solanum melongena*), and tobacco (*Nicotiana tabacum*). The potato produces stolons (or underground stems) that under certain environmental conditions enlarge to form tubers (the Potato Genome Sequencing Consortium 2011). Potatoes are propagated vegetatively through the transplantation of "seed potato," namely, the swollen stolon or tuber. The plant is predominantly grown as a source of starch, although it provides some protein, vitamins, and other nutrients.

Major Domestication Traits

Although there is only one domesticated species (*Solanum tuberosum*), there are thousands of cultivated varieties which display considerable genetic and morphological variation. Human selection under cultivation has favored size, shape, color, texture, and taste, including the reduction of bitter glycoalkaloids.

There is considerable diversity in the number and range of wild *Solanum* species in the Americas, many of which are tuber-bearing. However, the greatest diversity of potato cultivars is found in the central Andean zone of Peru and Bolivia. Indeed, the plant is generally considered to have been domesticated in the temperate climates of the central Andes (Harlan 1971; Brush et al. 1981; Hawkes 1990; Vavilov 1992; Spooner et al. 2005).

Although various hypotheses have been proposed, all suggest domestication from a group of morphologically similar, wild tuberous *Solanum* species – referred to as the *Solanum brevicaule* complex in the central Andes (extending from Peru to Argentina). The specifics of the hypotheses vary: most suggest multiple domestications from different members of the *Solanum brevicaule* complex across the central Andean region (e.g., Hawkes 1990), whereas others suggest a single domestication or monophyletic origin in Peru (e.g., Spooner et al. 2005). Potato is generally considered to be a cultigen, namely, it was domesticated through the introgression or cross-fertilization between two species rather than being descended from a single precursor.

The oldest archaeological evidence for potato domestication comes from the central Andean region. Macrobotanical finds of potato tuber fragments at Tres Ventanas caves in Chilca Canyon of coastal Peru have been claimed to date to the early Holocene, perhaps to 10,000 years ago (Engel 1970; Pickersgill and Heiser 1977). Given the morphological range in tuber-bearing *Solanum* species, some of these identifications may require more detailed analysis to determine species and domestication status more precisely. Perhaps tellingly, potato remains are almost absent from the archaeobotanical record from the central Andean region for the following 5,000 years or so; the next oldest sites yielding evidence of potatoes date to c. 4,500–4,000 years ago (see review in Hastorf 2007). Evidence for the likely cultivation of potatoes becomes more common from c. 4,000 to 3,500 years ago in the Casma Valley of Peru (Ugent et al. 1982; Ugent and Peterson 1988), tentatively identified at Waynuna in southern Peru (Perry 2007), as well as at other sites.

Potatoes are depicted on ceramics of Andean cultures dating to the last 2,000 years or so.

Over the last 500 years, potato has been distributed widely across the globe to be grown predominantly in temperate climates (Salaman 1949). Initially, only a narrow genetic range of cultivated potatoes was moved to Europe, but this has been deliberately expanded since the nineteenth century. The infamous Irish potato famine of the mid-nineteenth century was caused by blight (*Phytophthora infestans*), which in part was so pernicious due to a narrow genetic stock of potatoes cultivated at that time. The dependence of the Irish population on potatoes led to the major famine with potentially up to a million people dead and a larger number migrating overseas. Given the global significance of the crop, a recent international effort has been focused on sequencing the potato genome with a view of crop improvement to resist blight and other diseases (the Potato Genome Sequencing Consortium 2011).

The Potter's Wheel

Ina Berg
Department of Classics, Ancient History, Archaeology and Egyptology, University of Manchester, Manchester, UK

Introduction

The potter's wheel was invented in the 5th millennium BC in the Near East and spread across the Mediterranean into southern and eastern Europe during the late Bronze and early Iron Ages before also reaching Asia and, finally, the American

continent. The potter's wheel utilized new technological principles, namely, rotational kinetic energy (RKE) combined with manual force, to shape vessels. Initially, however, it seems that the wheel was only used to throw small shapes and medium or large-sized pots were made in stages using hybrid techniques. When utilized to its full potential, this invention has the ability to speed up production considerably. It remains a mystery why ethnographic studies consistently show that the potter's wheel is almost exclusively associated with male potters.

Definition

Scholars have conventionally defined potter's wheels either by placing greater emphasis on the device's design (Childe 1954; Evely 2000; Franken 1971; Holthoer 1977; Saraswati and Behura 1966; Streily 2000; Wood 1990) or on the speed/length of rotation that can be achieved (Arnold and Bourriau 1993; Foster 1959a; Rice 1987; Roux 2019; Scheans 1965; Thér et al. 2017). In reality, most scholars recognize that the two aspects need to be considered together as unaided rotation requires a stable and smoothly running flywheel.

Potter's wheels are traditionally divided into two categories: simple and double (or kick) wheels (Holthoer 1977) (Figs. 1 and 2). Both can reach a maximum speed of 220–230 rotations per minute (rpm), though most potting activities will fall within a range of 50–120 rpm. The simple wheel consists of one single, heavy wheel that serves both as the flywheel and the potting surface. It is activated by stick or by hand – either by the potter or an assistant. The momentum is stored in the heavy wheel which will gradually slow down as the potter works. A pivoting axis is set in the ground and, depending on its length, may also need stabilizing higher up. To achieve the necessary weight, they are normally made of stone or clay, though wood can also be used. The simple wheel can be constructed at any height, and potters may sit, squat, or stand to work on it. The double wheel is constructed of a light round upper throwing surface and a heavy flywheel below which are connected by a fixed vertical axis. The advantage of the double wheel is that potters themselves can adjust its speed seamlessly by kicking the flywheel at the bottom while constructing the pot on the small throwing surface on the top.

Potter's wheels need to be distinguished from rotary devices and turntables (or *tournettes*).

The Potter's Wheel, Fig. 1 Simple wheel from India. (Wikimedia commons; accessed 12/9/19)

The Potter's Wheel, Fig. 2 Kick wheel, Jaffa, Palestine, 1859. (Wikimedia commons; accessed 12/9/19)

A rotary device is not mounted on an axis and hence does not generate any rotational momentum. A rotary device might be a wooden or clay plate, bat, or a large clay sherd upon which a pot is being constructed. Early Bronze Age "mats" from Crete are good examples of this type (Evely 2000: 271–273 (Type 1)). A turntable is a device mounted on an axis which the potter or an assistant can rotate, but any momentum generated slows down quickly and does not allow the creation of an entire vessel. Turntables can be made of wood, clay, or stone. Roux considers prehistoric Mesopotamian and Palestinian stone-pivot arrangements to fall into this category (2019: 50; Roux and de Miroschedji 2009) (Fig. 3). The division of devices into rotary devices, turntable, and wheel is based on the assumption that only wheels can achieve sufficient rotational kinetic energy that would allow the wheelhead to spin for long periods of time despite the weight of the flywheel itself, the weight of the clay, and the pressure exerted by the potter while making the pot. However, in reality, the distinction between the different potting devices is rather fluid and imprecise.

Several physical phenomena impact on a vessel as it is being thrown on the wheel. These are the rotational kinetic energy (expressed in terms of angular velocity and the moment of inertia), as well as manual pressures. Angular velocity is the amount of rotation the wheel undergoes based on its speed and direction. The moment of inertia is the distribution of mass around an axis of rotation and refers to the opposition of the device to changes in speed of rotation. Calculations may include, for example, its weight, dimensions, and morphology. Hence, rotational kinetic energy is the rotational energy that the wheel exerts bearing in mind the speed of rotation and opposition to this rotation. Manual pressures are vertical and horizontal pressures of the potter's hands in relation to the malleable clay as she/he pulls up the vessel, thins the walls, and molds its shape by pushing inward or outward with one or both

The Potter's Wheel, Fig. 3 Levantine and Egyptian potter's wheels. (**a**) Canaanite-Israelite and Egyptian stone socket/pivot arrangements. (After Amiran and Shenhav 1984; Powell 1995); (**b**) Reconstruction of Canaanite-Israelite and Egyptian potter's wheel. (After Amiran and Shenhav 1984; Powell 1995); (**c**) Levantine stone potter's wheel. (After Roux and de Miroschedji 2009). To scale

hands. In contrast to common perception, centrifugal force – which exerts pressure toward the outside – does not play an active role in raising a vessel up; it only contributes negatively or positively by making inward movement harder or by supporting outward movement (Roux 2019: 76–83). A similar argument can be made about gravity which could also be considered a passive force in that it attracts a material toward the center of the earth and thus exerts downward pressure on the clay mass, but does not impact positively on the upwards throwing motion of a potter.

Excavations do not necessarily reveal potter's workshops or evidence of potter's wheels and archaeologists therefore must rely on macroscopic and microscopic traces on the pots themselves to deduce the use of a potter's wheel (Evely 2000: 269; Van As and Jacobs 2014: 89). There are several of these marks or traces.

The first of the macroscopic marks is the base (or central) spiral. This spiral is created when the potter applies first downward and then outward pressure with their fingers to open the clay ball and to create the base width of the vessel. It quite often leaves a raised central "pimple." Because the wheelhead of the potter's wheel offers solid resistance, the base spiral is normally well pronounced (Fig. 4a). The second feature is throwing grooves, also called rilling, on the outside and/or inside of the vessel wall. Rilling marks are best observed on the interior of restricted vessels. They can be shallow or deep and horizontal, concentric, or spiraling depending on the pressure, direction, and speed applied by the potter. The more even and continuous these grooves, the more likely they are made by throwing (Fig. 4b). Uneven or discontinuous rilling may hint at forming techniques that only utilize rotation for part of the manufacturing sequence (Courty and Roux 1995). When pots receive secondary treatments like smoothing, scraping, burnishing, or turning, rilling marks may be obliterated entirely. Thirdly, there are diagonal compression ridges in the neck region which occur when rotating clay is being pushed inward to create a neck. The fourth mark is the spiral cut-off pattern on the underside of the base. When the wheel is rotating while the potter is cutting the pot off with a string or wire, this action leaves a characteristic decentralized spiral pattern on the underside of the base (Fig. 4c). Stationary vessels leave linear marks. Cutting marks are often removed by subsequent treatment. Finally, there is a gradual thinning of the wall from the base to the rim. Unlike handmade pots which can display the same wall thickness from base to rim, wheel-thrown vases normally show a gradually reducing thickness as the lower section would otherwise collapse under the weight of the upper section (Fig. 4d).

While all these marks and features are clear evidence of the utilization of some rotating device at a particular stage during the making of a vessel (e.g., the base, the neck, or removal of the pot), none of these marks are incontrovertible or unambiguous evidence of throwing as turning devices can leave similar patterns nor do they confirm that the entire pot has been made on the wheel. Absence of distinct traces of hand-forming techniques, such as coil seams, mold seams, or uneven wall thickness as a result of paddle and anvil action, can aid our interpretation.

In addition, there are further – more subtle – macroscopic indicators of wheel-throwing. Firstly, there is the pot's symmetry. Handmade pots can take on any shape, regular or irregular. In contrast, pots thrown on a wheel are, by the very nature of the device, symmetrical and regular in shape. Secondly, as wheel-throwing requires clay to be wet in order to make it malleable, this can lead to unintended stretching of the clay which is visible as small cracks in the wall. Finally, the existence of self-slip is indicative of the use of water during the manufacture which creates a very thin layer of liquid clay that settles on the walls of the vessel. It may be removed by subsequent surface treatment or decorating.

Most of these indicators are polysemic and can be the result of entirely different forming techniques. However, the most reliable ones for throwing are the base spiral and reducing thickness between the base and rim as they are less likely to stem from other manufacturing techniques.

Microscopic investigations, while time-consuming, costly, and limited in sample size,

The Potter's Wheel, Fig. 4 (**a**) Base spiral. (**b**) Rilling. (**c**) Cut-off spiral pattern. (**d**) Gradual thinning of wall from base to rim

can be very helpful in determining whether or not a pot was wheel-thrown by evaluating porosity (volume, size, orientation, frequency, distribution and degree of connection with other pores) and inclusions/temper (orientation and distribution of elongated inclusions or temper). Porosity is impacted by the amount of water and temper/inclusions used, the type of temper/inclusions, the content of the clay matrix, kneading, preparation and firing – as a consequence, porosity is a

good indirect indicator of forming technique. Petrography, X-radiography, and, most recently, high-resolution X-ray microtomography have shown that handmade and wheel-thrown vessels can be confidently identified based on the above criteria and that distinction between different wheel-utilizing techniques and wheel-throwing is also often possible (Berg 2008; Karl et al. 2013; Pierret et al. 1996; Thér 2016).

Scholars have identified the speed (in rpm) and/or the duration of unaided rotation (often called the "momentum") as key characteristics of a true potter's wheel leading to a supposed division of wheels into "slow" and "fast" types (Holthoer 1977; Roux and de Miroschedji 2009; Orton et al. 1993: 120–125; Rice 1987: 132–135; Childe 1954), with "slow" wheels not considered proper potter's wheels. The assumption is that rotational kinetic energy (some scholars mistakenly identify it as centrifugal force) only starts acting upon a vessel when the wheel reaches a particular speed (rpm) and that pots made at slow speeds therefore are not "thrown." The minimum speed required to attain RKE has not yet been demonstrated experimentally or theoretically. Various speed ranges for throwing pots are mentioned in the literature but normally lie around 80–150 rpm (Childe 1954; Amiran and Shenhav 1984: 108; Doherty 2012: 17; Evely 1988: 118; Roux 2010). However, experiments have demonstrated that pots can indeed be thrown at very low speeds and hence that rotational kinetic energy acts upon clay at all speeds: 36 rpm was sufficient to throw a 10 cm tall cup (Berg 2013: 116); 15–20 rpm were used to form a small pot (Doherty 2012: 17); and a medium-sized vessel was thrown at 60 rpm (Foster 1959b: 62) even when the potters themselves consider the task time consuming, more laborious or boring. The presumption of a minimum speed at which rotational kinetic energy jumps into action also ignores the reality of potting, whereby the potter will vary the wheel speed depending on the stage of the throwing process and the size of the vessel: centering is done at higher speeds than pulling up or shaping; and the larger the vessel and the greater the clay mass, the slower the speeds (Gandon et al. 2011).

The second assumption is that a wheel has to spin for a considerable amount of time to throw a pot. However, ethnographic data have shown that, for example, experienced potters only need approximately three and half minutes to complete a pot of 47.5 cm × 20 cm × 22.5 cm (Saraswati and Behura 1966: 54). A household factory potter in Spain could throw 100 small items in an hour and a Mexican potter could make one food bowl every 47 s on average (Arnold 1985: 208, 244–245). Thus, when high speeds can be obtained, the necessary duration of unaided rotation to complete a pot is considerably shorter than standard accounts seem to imply. Where the moment of inertia is too great, the use of an assistant who keeps the wheel in motion can be used to overcome any disadvantages.

Finally, we must discard the common assumption that the potter's wheel is exclusively associated with wheel-throwing. As the case studies below demonstrate, a wide range of hybrid forming techniques combine handmade techniques with the wheel at different stages of the forming process (Courty and Roux 1995). All of these may utilize the potter's wheel as a device, but do not necessarily use it to its full potential. Instead, they may use it more like a turntable by using it at lower speeds or for shorter periods of rotation.

Historical Background and Future Directions

From the 1950s to the 1990s ethnographic studies of traditional potters were at the forefront of researchers' endeavors. We now possess a very comprehensive library of worldwide case studies (Arnold 1985; Foster 1959a, b; Kramer 1997; Saraswati and Behura 1966), and there is a sense that additional examples will not dramatically change our existing knowledge base. Experimental archaeology was another valued avenue of exploration, much of it focusing on reconstructing potter's wheels to understand their design features, physical potential, and limitations (Arnold and Bourriau 1993; Roux and Corbetta 1989). We have now acquired a solid understanding of these

factors and, thus, experimental work has changed direction to helping us understand the very essentials that underpin the utilization of the potter's wheel, such as the nature of the physical forces acting upon the wheel and establishing the level of skill potters have, and how this impacts on their use of the wheel (Roux 2019; Gandon and Roux 2019; Gandon et al. 2011). Despite decades of research into the potter's wheel, there is still much that is unknown about the very core forces and aspects, and it is in this subject area where future contributions to knowledge will have the greatest impact on our understanding. With finds of potter's wheel relatively rare but pots abundant, another strand with great future potential are investigations into the features encoded into pots that were made on the wheel to see whether we can work backward from the product to the device (e.g. Berg 2008; Choleva 2018; Jeffra 2013; Thér et al. 2017). Again, experimental archaeology will take a leading role here by working with replica control groups before applying the findings to ancient material. All of this will, of course, involve a multitude of scientific and social science disciplines that will make key contributions to our overall comprehension of the device.

Key Issues/Current Debates

Emergence of Innovation

It is commonly assumed that there was an evolutionary progression from rotating devices to turntables to the wheel, as potters gradually acquired the skill to harness rotational kinetic energy ever more effectively. The eventual invention of the potter's wheel is traditionally linked to the onset of mass production, with the wheel specifically acting as a device to speed up production and produce standardized shapes (Childe 1954; Nissen 2006; Saraswati and Behura 1966: 16). However, while scholars recognized that the wheel does of course speed up production (Arnold 1985: 208), recent work in Egypt and the Near East has shown prestige and technical exclusivity – rather than speed – to have been the driving forces for the emergence of the wheel (see also Thér et al. 2017 for central Europe and Crewe and Knappett 2012 for Cyprus; Choleva 2018 for mainland Greece; Berg 2007 for Melos). The marketization of speed and commercialization of the wheel are later developments (Foster 1959a; Streily 2000: 233).

Evidence of the social context of the emergence of the potter's wheel in Egypt has been collated by Doherty (2012). The earliest credible scenes of potters using potter's wheels can be found in the Tomb of Ty at Saqqara (Fig. 5) and Tomb of Ptahshepses at Abu Sir dated to the 5th Dynasty of the Old Kingdom (ca. 2500–2300 BC). Statuettes, models, and written manuscript also date back to this period and, together, indicate that these potters were under the control of Egyptian royalty and nobility. First evidence of wheel-thrown pottery is linked to the 4th–5th dynasties (2600–2300 BC) when it became popular for Pharaohs to build monumental pyramids which incorporated chapels dedicated specifically to the nourishment of their spirit (*ka*) in the afterlife. Daily liquid and solid offerings to the Pharaoh's *ka* were made in miniature, wheel-thrown cups produced in vast amounts. Prior to the introduction of the potter's wheel, specialist potters already produced standardized funerary vessels at a large scale mainly using the mold technique. Increasing the production could easily have been achieved by adding more workers. In contrast, the first pottery produced on the wheel consisted of shapes exclusively used for the Pharaoh's funerary state-controlled activities before gradually being disseminated into private elite contexts. The elite meaning associated with the potter's wheel is further encapsulated by the use of basalt in the construction of the wheel bearings, a prestigious and rare stone requiring the expertise of stone masons and previously exclusively used in the manufacture of religious statuary.

An exclusive elite craft context for the use of the wheel is also observed in the southern Levant where the potter's wheel is first used during the Late Chalcolithic (4500–4000 BC) for the manufacture of V-shaped bowls, small ceremonial bowls used in ritual activities. Knowledge of the potter's wheel ceased immediately following the collapse of the societies, and the technology only

The Potter's Wheel, Fig. 5 Tomb of Ty, Saqqara, Egypt, showing potter working on a wheel (c. 2450–2300 BC). (Doherty 2012: Fig. 2.2. *Image reproduced courtesy of S. Doherty*)

reemerges centuries later (Baldi and Roux 2016; Roux 2003). Mass production does not appear to have played a role either in northern Mesopotamia where wheelmade bowls make up less than 1% during Late Chalcolithic 2 (3900–3800 BC) at Tell Feres al-Sharqui. Similar to the Levant and Egypt, most of the bowls were found in a central elite building, Importantly, these bowls were made in by wheel-coiling rather than wheel-throwing (Baldi and Roux 2016).

Adoption of Invention and Transmission of Technology

Invention of a product or devices does not automatically guarantee its successful transmission. This also applies to the potter's wheel where scholars have observed both the disappearance of the technology after initial use and widespread adoption. The former scenario is exemplified by the abovementioned Late Chalcolithic ceremonial V-shaped bowls from the southern Levant. When these Chalcolithic cultures collapsed in Early Bronze I (4th mill BC), wheelmade pottery also vanished. It only reemerged in Early Bronze II–III (3rd mill BC), though only a small number of vessels were made with this technique and there is no spread of the technique beyond the confines of a restricted set of specialists. At the end of the 3rd millennium BC (Early Bronze IV), cities collapsed and wheelmade pottery disappears again, only to reappear a few centuries later to establish itself as the dominant pottery forming technique by Middle Bronze II (mid-2nd mill. BC) (Roux 2010).

Invention of the potter's wheel followed by keen widespread adoption is visible on Bronze Age Crete (Fig. 6). Here, experimentation with the potter's wheel in Early Minoan III/Middle Minoan IA leads to its adoption in Middle Minoan IB where it is used in the making of cups, in particular. The initial use is widespread and immediate, extending to palatial and non-palatial sites across the entire island, although it takes several centuries for potters to acquire the necessary

The Potter's Wheel, Fig. 6 Reconstruction of Minoan potter's wheel. (After Evely 2000; Morrison and Park 2007/8)

know-how to also make large pots on the wheel (Crewe and Knappett 2012).

As these two case studies show, adoption scenarios of the wheel can range from widespread to aborted. Roux (2010) offers an explanatory framework which examines to what degree innovation systems are fragile/robust or closed/open. She argues that the transmission of an innovation is, in part, dependent on the size of the network, skill level and production context of the craftspeople involved. Fragile technological systems are restricted in the number of participants and therefore cannot withstand transformations of the societal structure. In contrast, robust systems have transmission networks sufficiently large to weather any socioeconomic storms. Closed systems have a strong relationship between the producers and the technological task, but do not interact with other production units. Open systems are characterized by transfer and borrowing between production groups.

In the context of V-shaped bowls, specialists were few in numbers, highly skilled, attached to elites, and producing pots specifically for elite consumption. When these elites collapsed, so did the production of the special function V-shaped bowls, leading to the disappearance of the potter's wheel. The system here was fragile and closed, leading to an interrupted development. In contrast stands Minoan Crete where the skills were widespread among a highly skilled, large potting community that served both palatial and non-palatial consumers. As a consequence, the potter's wheel flourished. The Cretan scenario is thus representative of a robust, open system with a linear pattern of transmission.

A number of additional factors have been referenced to explain the failure of adoption of the wheel in various contexts across the world. Arnold, for example, recounts the efforts of the Mexican government to increase the efficiency and quality of pottery production in the town of Ticul in the 1930s (2008: 238–242; also Arnold 1985: 222–223). At this time, local potters were using the k'abal, a traditional turntable, to make pots. Despite sending an experienced potter who ran a workshop with five kick wheels for 4 or 5 years, the potter's wheel was not adopted by

the local community of potters. The disadvantages highlighted were (a) the price of the wheel which was well beyond the reach of a local potter's income, (b) the local clay was considered too coarse and unsuitable, (c) potters were used to working barefoot which resulted in abrasions and injuries of their feet when kicking the flywheel, and (d) the wheel was incompatible with existing motor skills and used different muscle groups. In addition, the organizational setup, including the sexual division of labor, may be inconsistent with the new technique. For example, the introduction of the potter's wheel in Guatemala was unsuccessful, argues Arnold (1985: 222–223), because pots had traditionally been made by women on a part-time basis alongside other household activities. When the wheel was introduced, it led to no change among women potters. Instead, the wheel became an entirely separate craft sphere performed by men. Strict social sanctions against innovation can also prevent change. Such sanctions were observed in Chinautla, Guatemala, between the 1950s and 1970s and led to a strict replication of the traditional pottery repertoire and strict prohibitions on innovations. Unfavorable industrial conditions may also make adoption less likely – Rajasthan potters mentioned the frequent power cuts that interfered with the use of their electric wheels (Kramer 1997: 62).

However, the potter's wheel, when used for proper wheel-throwing, can also bring many advantages. It produces even and symmetrical vessels, it allows the production of a vessel in a matter of minutes and can thus maximize turnover, and it speeds up mean production times – Arnold (2008: 244) estimates that a wheel can make production between twice and five times faster than a turntable or mold – although this theoretical increase in production speed must be weighted against a greater time investment at other points during the manufacturing sequence, such as collection and preparation of finer clay. Most importantly, however, for an adoption to be successful, the motor habits and work position must be compatible with previous practices. Foster therefore notes that it is often easier to train non-potters in a new technique than converting experienced potters from a traditional technique to wheel-throwing (1959a). In addition, Thér and his colleagues have highlighted the performative aspects of wheel-throwing, such as the rotation of the wheel, the gradual shaping of the vessel, the obvious grooves on the surface, which can appear highly attractive, if not magical, to the non-specialist when watching the manufacturing process or when touching the final product (2017).

The advantages of the potter's wheel are less clear-cut when the power of rotational kinetic energy is not understood or when RKE is not used to its full potential, for example, when the wheel is used more like a smoothly running turntable or when pots are created in stages, as is typical for wheel-coiling (Foster 1959a: 100–109; Arnold 2008: 242–243) (Fig. 7). The use of the potter's wheel for wheel-coiling is a common phenomenon in the Old World where scholars have argued that the first use of the wheel was actually to make wheel-coiled vessels rather than wheel-thrown ones (Choleva 2018 for prehistoric Greece; Thér et al. 2017 for Iron Age Europe; Jeffra 2013 for Minoan Crete; Roux 2010 for the Near East). Roux (2010) conceptualizes the emergence of the potter's wheel in two stages: its initial use was for wheel-coiling and, later, for wheel-throwing. Because the potter's wheel, even when used incompletely for wheel-coiling, introduces an entirely new physical principle, it represents a jump in the history of innovations. It is a "discontinuous innovation" because potters would have to acquire an entirely new set of motor skills to use a device that retains RKE for long periods of time using entirely different hand motions (Roux 2010). Because new motor skills need to be developed, scholars have stressed the importance of a face-to-face interaction to ensure complete transmission of the innovation – learning how to throw sections of a pot, even if they were coiled first, requires the acquisition of cumulative bimanual skills (Roux and Corbetta 1989) through a lengthy apprenticeship. Being a highly complex skill, developing a high level of expertise in wheel-throwing is estimated to take up to 10 years (Ericsson and Lehmann 1996). On the positive side, when an experienced wheel-throwing potter is confronted with a

Common Forming Techniques

Type	Name	Definition
Handmade *Pots made without the help of rotational kinetic energy*	Pinching	Squeezing a clay ball between fingers and thumb, and then thinning the walls. Mostly used for small open vessels; can also be used to begin the base of larger vessels or as a finishing technique to even out walls.
	Drawing	Starting from a lump of clay, the walls are pulled or squeezed upwards with the hands to create the desired shape. Frequently combined with coiling where coils are pulled up in stages.
	Coiling	Rolls of uniform thickness are created and then used to build up the vessel shape. The pot may vary in wall thickness along the horizontal and/or vertical axis and coil seam junctures. Often combined with other techniques, such as drawing or wheel throwing.
	Slab building	A vessel built up of joined flat slabs. Particularly suitable for large vessels.
	Molding	A flat 'pancake' of clay is prepared and placed into a plain or decorated mold. As the clay shrinks away from the mold, it retains the desired shape.
	Wheel coiling	Rotational kinetic energy (RKE) is applied to a vessel originally made of coils and can be introduced at different stages of the forming process. At its most basic, pots are made by coiling and then thinned or smoothed on the potter's wheel. At its most advanced, a coil is added and 'thrown'. Common features mirror those of wheel-thrown pots, but are less continuous and regular.
Wheelmade *Manufacture involves the use of rotational kinetic energy*	Wheel throwing	The potter's wheel runs at speeds sufficiently high to develop RKE which is used by the potter to pull up and shape the clay with bilateral movements.

The Potter's Wheel, Fig. 7 Common forming techniques with and without use of rotational kinetic energy

different wheel or new shapes, they are able to adjust to these challenges easily by applying and, if necessary, modifying existing hand positions (Gandon and Roux 2019). Wheel-coiling skills, in contrast, are less demanding but may still require a lengthy period of direct interaction between expert and learner.

If we accept that the first potter's wheels were not exploited to their full potential, then this realization provides additional support that the introduction of the wheel was unrelated to the desire for mass production or a more standardized product – both of which require that the potter's wheel was utilized to its greatest potential. Thus, as Foster (1959a: 104, 109) would argue, it was not the wheel itself that brought about technological or social change, but rather acted as a device that could be utilized to implement change already in motion.

International Perspectives

The potter's wheel can be found in all corners of the world. The specific design may vary, but the

applied principles remain recognizable. As we have seen above, it was invented in the 5th millennium BC in the Near East (Roux 2010) and spread across the Mediterranean and north and eastern Europe during the Bronze and early Iron Ages (Thér et al. 2017; Crewe and Knappett 2012; Doherty 2012). It is widespread in Asia, though the precise date of introduction is unclear. In the Americas, the wheel was first introduced by the Spanish (Arnold 2008: 238).

Scholars normally assume that wheel was introduced in a supposed evolutionary sequence from bat to pivoted turntable to simple wheel to double wheel. However, it has become amply clear that the wheel often was not immediately used to its full potential, and hence the period of initial innovation and stage of widespread use do not typically overlap. Likewise, it is commonly observed that the different devices are used simultaneously within the same cultural setup.

As Foster (1959a: 116) already recognized some time ago, one of the great mysteries of history is the potter's wheel's well-established correlation with male potters. Worldwide ethnographic studies have shown that 80% of traditional potters are female. Nevertheless, the introduction of the wheel almost always leads to the involvement of male potters with women continuing to manufacture vessels by traditional hand-forming methods in the home. When women use the wheel, it is for wheel-coiling only (Vincentelli 2003). The proverbial exception to the rule are female potters from El Porvenir in Honduras who – due to limited agricultural potential, men's long absences from the community, and easy access to potting resources – took up wheel-throwing commercially to ensure the financial survival of their households (Mouat and Arnold 1988). Whether the typical gender division also applies to prehistoric potters is a matter of speculation. Foster (1959a: 116) hypothesizes that this may be due to the physical strength that is required to set and keep the wheel spinning and throwing heavy clay. However, given the evidence of modern female artisan potters, the involvement of women in many other physically strenuous stages of the pottery production, and women's general participation in demanding tasks, such as agriculture, textile manufacture, and childcare, this argument seems unviable (Rice 1987; Kramer 1985). Instead, Kramer (1985) suggests that economic aspects interact with religious or ideological traditions, such as supply and demand patterns, employment types, household organization, access to raw material resources, capital and time, apprenticeship patterns, or the need for mobility and visibility of potters. Arnold (1985: 99–108), in contrast, draws attention to the strong relationship between men and agricultural activities, arguing that, when this link is broken, men will turn to alternative income-generating resources, such as wheel-throwing, while women remain associated with household tasks and handmade production which are more easily scheduled around agricultural and childcare tasks.

Poverty Point, Archaeology of

T. R. Kidder and Kelly Ervin
Department of Anthropology, Washington University in St. Louis, St. Louis, MO, USA

Introduction

The Poverty Point site in northeastern Louisiana is famous for the largest known monuments built by hunter-gatherers. Designated a UNESCO World Heritage landmark in 2014, Poverty Point is a 3-square-kilometer earthwork complex of two massive mounds, several conical and flat-topped mounds, and six elliptical ridges enclosing a 17.4-hectare plaza where numerous circles of large wooden single-set posts are buried beneath cultural fill (Fig. 1). The Late Archaic Poverty Point culture of the lower Mississippi River Valley (c. 2050–1150 cal. BCE) exhibited an unprecedented form of social organization indicated by the accumulation of exotic lithic material measured by metric ton and the construction of extraordinary monumental architecture at a scale that surpasses most monuments built by agriculturalists in North America. Subsistence studies demonstrate that the inhabitants of Poverty Point and contemporary sites were entirely dependent on the consumption of wild plants, animals, and fish. These qualities set Poverty Point and related sites apart from other Late Archaic contemporary sites in eastern North America.

Definition

The term Poverty Point culture (Webb 1982) has been applied to sites dating to the same time period in the Mississippi Valley from southeastern Missouri to the Gulf Coast. Poverty Point "culture" refers to the use of common material traits, most notably clay cooking balls and certain forms of hafted knives or projectile points. Although the

Poverty Point, Archaeology of, Fig. 1 LiDAR-derived DEM showing Poverty Point earthworks

Poverty Point type site is centrally located among Poverty Point culture settlements within the region, we suspect that political, social, and linguistic relations were complex, fluid, and not dependent on political direction or control from the Poverty Point site itself.

Key Issues/Current Debates/Future Directions

Poverty Point culture is entirely unique for any point in American Indian history. On a global scale, the people who constructed and inhabited

the type site stand out for building the largest hunter-gatherer settlement anywhere, for erecting what in context was massive monumental architecture, and for participating in a complicated and well-established long-distance exchange network that spanned much of eastern North America resulting in the accumulation of tons of foreign raw material (in fact, all lithics found at the site must be imported, because there are no naturally occurring lithic sources within 50–75 km). We suspect the movement of exotic materials was coordinated among Poverty Point-affiliated settlements within the valley and along its edges. Spatial analysis of the settlement plan shows a multi-tiered distribution of site sizes organized around the centrally located type site. In these regards, the organization of networks that integrated culturally diverse populations and materials over such a large geographic area is considered unique among hunter-gatherer groups.

Jaketown and Other Poverty Point Culture Sites

Although much of the focus has been on Poverty Point, there are a number of contemporary communities of varying sizes located in and around the floodplain of the lower Mississippi River Valley. Although no other site within the regional network is even half the size of Poverty Point, Jaketown, Claiborne, and Neimeyer-Dare stand out as considerably larger than the majority of all known Poverty Point sites (Fig. 2). These larger sites are hypothesized as distributional centers that mediated the flow of goods and people inward

Poverty Point, Archaeology of, Fig. 2 Map of the lower Mississippi River Valley region showing the location of Poverty Point and distributional centers

through the valley and toward Poverty Point. The Jaketown site in west-central Mississippi is the earliest securely dated Poverty Point settlement, having been established c. 2050 cal. BCE. The material culture assemblage in the early deposits at Jaketown contains all of the hallmarks of Poverty Point culture: baked-clay objects, lithic raw material from a wide trade network, lapidary art, and distinctive narrow-necked projectile points. Between c. 1550 and 1450 cal. BCE and before the massive earth-moving events took place at Poverty Point, the inhabitants of Jaketown were building earthen mounds and had constructed the second largest contemporary Poverty Point monuments in the lower Mississippi Valley. The Claiborne site near the mouth of the Pearl River also has very early radiocarbon dates, but from poorly defined stratigraphic contexts. However, this site has classic Poverty Point material culture and was arguably a distributional center for importing goods flowing east to west along the Gulf Coast.

Many small Poverty Point sites have been explored, but few are in great detail. These sites are assumed to be residential communities. At the Copes site in northeastern Louisiana, only 14 km southwest of Poverty Point, faunal and floral evidence indicates that the occupants lived at the site all four seasons of the year (Jackson 1986). The occupants were consuming a variety of wild foods, notably fish and deer, as well as collecting acorn and especially pecan, and unidentified grasses. At Copes and other small residential sites throughout the lower Mississippi Valley, the inhabitants were participating in the long-distance exchange network that is one of the hallmarks of Poverty Point culture. At many small sites, nonlocal lithics coming from distances of more than 100 km make up 50% or more of the total assemblage.

The Poverty Point Site

The Poverty Point site is located on the eastern edge of Macon Ridge, a 5-m-high Pleistocene terrace overlooking the Holocene floodplain of the Mississippi River (Fig. 1). Bayou Macon, a small local drainage, is located at the base of the terrace and forms the eastern boundary of the site. To the north, west, and south lies a flat to undulating terrace surface broken by small streams and some ponds. The site is composed of a c. 1000-ha. core area of dense habitation remains, earthen ridges, and mounds with contemporary settlement debris in concentrated patches spread over 6–7 km^2. The southern and northern boundaries are marked by earthen mounds, but these mounds were either built at an earlier date (lower Jackson Mound on the southernmost end of the site was built c. 3000 cal. BCE) or a later date (the Jackson Place Mound group to the immediate south was likely built between 1000 and 1200 CE), or their age of construction is unclear (Motley Mound on the northern end is assumed to have been built during the Poverty Point-era occupation but has never been directly dated). Smaller settlements – presumably villages – with direct evidence of contemporary occupation are found to the east along the banks of sluggish bayous draining the Mississippi River floodplain and more rarely to the west, north, and south along the terrace surface. Contemporary settlements are found in an area encompassing roughly 2000 km^2 around the Poverty Point site, and sites of the same age with some evidence of Poverty Point cultural affiliation are located at greater distances within the Mississippi River embayment and along its tributaries.

The core area of occupation is marked by the presence of six "C-shaped" concentric earthen ridges with their ends facing east leaving a large open area (often referred to as a plaza). These ridges averaged 2–3 m tall and were approximately 30–40 m wide at their base. Five mounds are found in the core area. The largest, Mound A, stands 21 m tall at its summit and slopes down to a flat terrace 10 m above the surrounding terrain. The mound is roughly "T-shaped" and measures 211 m north to south along the top of the T and 207 m east to west. To the north of Mound A is Mound B, a conical mound some 5–6 m tall with a base roughly 55 m in diameter. Mound C is located within the open area or plaza along the edge of the terrace, and today the apex is conical and stands only 2–2.5 m tall. This mound is elongated on its north-to-south axis, but much of the

eastern side of the mound may have been lost to erosion. Mound D rises 2 m above the plaza and is located along the terrace on the south edge of the open plaza area. Mound E is located due south of Mound A and is a 3-m-high rectangular platform with a flat summit. Mound F, which was only recently recognized, is a low conical earthwork 1.5 m tall located along the eastern edge of the terrace just north of the earthen ridges.

Mounds A, B, C, and F are dated and were built during the Poverty Point-era occupation. Mound D was likely built by historic Euro-American settlers as the platform for nineteenth-century burials. Mound E is not yet dated but based on soil profile development could date before the Poverty Point-age occupation, although a contemporary occupation cannot be ruled out.

As befits a large site, Poverty Point has a complicated occupation history. Surface-collected artifacts show that the earliest occupation within the site area goes back to the Paleo-Indian period (c. 11,000–8000 BCE), and there are modest quantities of Early (c. 8000–5000 BCE) and Middle (c. 5000–2000 BCE) Archaic remains scattered across the eastern edge of Macon Ridge. During the late Middle Archaic and early Late Archaic periods, there is an apparent occupational hiatus c. 2800–1500 cal. BCE. Beginning c. 1500 cal. BCE, a substantial Poverty Point culture-affiliated occupation occurred across much of the core area of the site, most notably along and near the eastern edge of Macon Ridge. At this time of initial occupation, the construction of earthen monumental architecture was limited. So far, only Mound B has been dated to this initial occupation period. Recent geophysical survey and limited test excavations in the open plaza area indicate that the earliest inhabitants were erecting large 25–65-m-diameter circular structures made up of 60–70-cm-diameter single-set posts. Based on their size and the absence of support posts within the circles, it is unlikely these were roofed structures. These features were eventually dismantled and the posts removed. The function of these features is unknown, but their size and the use of large posts indicate a considerable investment in labor. These can be considered monumental architecture, especially in the context of a purely hunting, fishing, and gathering subsistence lifestyle.

This initial occupation episode is widespread, and contemporary remains are found beneath the plaza and under what would become the ridges. Limited radiocarbon dating of these remains suggests the occupation lasted some 200 years, from c. 1500 to 1300 cal. BCE. At present, it is unclear if this was a permanent village or if these remains mark repeated visits to the site over the duration of the dated occupation span. Early inhabitants are notable for making and using a distinctive Poverty Point material culture, including the ubiquitous baked-clay cooking balls ("Poverty Point objects" or PPOs), hafted knives or projectile points, microlithic tools, and lapidary items such as beads and bannerstones. The site's inhabitants were importing lithic materials from very long distances at this time. One of the most prominent lithic raw material types in these early deposits is Burlington chert, sourced to the central Mississippi River area around modern St. Louis, Missouri, nearly 700 km to the north of Poverty Point. One study found that in seven test pits that penetrated to the earliest occupation zone, Burlington chert remains (tools and debitage) from the initial occupation levels weighed nearly 16,000 g. In contrast, only 4000 g of the so-called local pebble chert, which is derived from basal gravels along the edges of the Mississippi Valley 50–75 km distant from Poverty Point, was recovered from the same contexts. At the time of initial occupation, other lithic sources were being tapped but in much smaller quantities. Still, the network of chert imported to the site encompassed a good deal of the Mississippi Valley and its tributaries.

Beginning c. 1300 cal. BCE, the site underwent a dramatic transformation. The most notable occurrence was the construction of the six earthen ridges and some of the mounds. Associated with these physical changes are shifts in material culture use and alteration of the raw material resource network. Although the data should be understood as provisional, because there are relatively few radiocarbon dates, the sequence of events leading to the radical reconfiguration of the site appears to begin with the termination of Mound B and the dismantling

of the single-set post structures within the area known as the plaza. Mound B, which had begun its life as a flat-topped platform mound, was covered with a thick mantle of earth, and the mound and its immediate surroundings seem to have been abandoned and never used again. Similarly, the single-set post features were carefully taken apart and the postholes filled.

Following these terminations, several important additions occurred. One is the beginning of the use of Mound C. Here, a series of thin (usually only a few cm thick) use or occupation surfaces were created, briefly used for unknown purposes, and then capped with carefully selected fills. This process of construction-use-fill was repeated multiple times creating a low rise (the shape is not currently known because of erosion on the east side of the mound). Mound C began as a low rise (possibly a platform) and was used for perhaps 100 years before being capped by the addition of a conical mass of earthen fill that covered the underlying use surfaces. This fill was peculiar in that it was not midden-stained or organically enriched but nonetheless contained abundant artifacts.

At the same time that Mound C was being erected and used, the concentric ridges were being built. The precise chronological relationships among these ridges are not clear at present – they may have been built in some order or may have been constructed more or less at the same time. In any case, they were built quite quickly, most likely within a generation. They were created by borrowing earth from areas immediately adjacent to the ridges, creating a shallow ditch between each ridge. The ridges are assumed to have been built to support houses or structures on their surfaces, but modern agriculture and over 3000 years of erosion and soil development have obliterated any obvious evidence of habitations – although some features, notably fire pits and earth-oven cooking pits, are known to occur. Artifacts are common on the ridges, their flanks, and the ditches at their bases. The surface of the site today is densely covered with artifacts, and a longtime collector amassed a surface collection in excess of 50,000 items that are provenienced by ridge and sector. Spatial analysis of this material demonstrates clear differences in the distribution of artifacts, and these differences appear to map onto the ridge and sector built environment. The spatial distribution of particular artifact classes further suggests that social differences among the inhabitants, or perhaps activity areas, were organized by the pattern of ridges and sectors. At roughly the same time as the ridges were being built, and after the initial surfaces of Mound C were deposited, the inner or plaza part of the site was covered with up to 75 cm of fill, creating a level surface and burying the post features previously erected on the ground surface.

Of the final construction activities at the site, the erection of Mound A is the most impressive. This mound, which is the second largest earthen monument in the United States, was built at the western edge of the outermost ridge. Excavations and coring of the mound demonstrate that much of it was constructed over a seasonally wet, swampy depression roughly 1–2 m deep. There is a clear sense of the construction sequence for Mound A. First, the vegetation of the swampy depression was burned, and then immediately after, a 5–15-cm-thick layer of tan to white fine silt was deposited across the swampy depression. The mound was then erected very rapidly. We believe that the western conical portion of the mound was built first. This part was built on the western edge of the swampy depression, and only part of it covers this feature. The western cone was constructed with distinctive, fairly homogenous soils that appear mined or borrowed from the surface or near the surface of Macon Ridge. The platform along the east end of the mound was then added on. Here, the soils are more heterogeneous and appear to come from contexts deeper within Macon Ridge. Shallow depressions to the north and to the west of the mound are likely borrow areas. Once the cone and platform were built, a ramp was added to join the two earthen features.

Three radiocarbon dates from short-lived plant charcoal, and a buried root at the base of the

platform dates the onset of construction to a mean age of 1252 cal. BCE. Our data indicate the mound was built very rapidly. Once construction started, there is no evidence it ceased until the mound reached its full form. There are no cultural stages, natural soil horizons, or erosion features within the mound except at the base of the ramp joining the cone to the platform. The absence of erosion features is especially notable, because the mound is made of reworked loess, which is especially susceptible to erosion, and the site is located in a humid-temperate region where rainfall is abundant, even in the driest months. We suspect the mound was built in as little as 3 months to probably not much more than a year. It certainly was not erected over multiple years or generations. With a volume of about 238,500 m^3, this duration of construction implies a workforce ranging from c. 1000 to 3000 laborers plus families. The function of the mound has never been established. The surface of the mound and its flanks are nearly devoid of artifacts, suggesting that if the mound was used for some purposes, the inhabitants were careful not to leave behind material culture residues.

The Poverty Point site was abandoned not long after the construction of Mound A. By c. 1150 cal. BCE, there were no longer any inhabitants who were leaving traces of occupation. The abandonment of the site coincides with an apparent decline in occupation intensity throughout the lower Mississippi Valley. Similar population declines are noted across much of eastern North America, and there is a large-scale transformation of cultures from Late Archaic to Early Woodland. Climate change and associated flooding throughout the Mississippi Valley are hypothesized to account for the apparent demise of Poverty Point and the so-called Poverty Point culture (Kidder 2006).

Most explanations for Poverty Point's genesis and reproduction share the underlying assumption that the site exists to fulfill an economically utilitarian function. The dominant assumption is that Poverty Point is an oversized town that takes its economic utility from the need to import lithics into a region where no lithics exist. Alternate models have posited that the site served to facilitate the exchange of economically valued goods among far-flung communities. The earthworks of Poverty Point have similarly been situated in a utilitarian framework. For Gibson (2000), the mounds represent physical manifestations of magic that buffer against a metaphysical but potentially real threat to the health and wellness of the community. To Hamilton (1999), on the other hand, the construction of mounds diverts human energy from reproduction to production and thereby acts to prevent overpopulation in the face of uncertain economic returns. Another perspective (Greenlee 2013) claims the Poverty Point earthworks were built as a costly signaling expression to communicate ownership of resources between competing groups.

The actions of the people who inhabited or visited Poverty Point, however, defy purely rational economic models related to lithic procurement and/or resource-buffering scenarios. Functionally unnecessary exotic lithics were imported in vast quantities when local stone was available within a more reasonable distance; steatite vessels were brought in when local pottery was available and nonlocal pottery when local pottery and/or steatite was accessible. The production of nonutilitarian items (e.g., beads, quartz crystals, oversized bifaces, and bannerstones) indicates behavior beyond economic rationale that has been ignored or undervalued. Compared to the amount of material imported to Poverty Point sites, little tangible is exported; thus, Poverty Point appears to be drawing large numbers of people and material to the site from across the Southeast.

Earthwork construction was functionally "nonutilitarian" as well. Most Poverty Point-age mounds did not support structures, burials, or the accumulation of post-construction occupation debris flanking or atop the construction stages. Instead, we suspect that building activities were highly ritualized events involving extremely complex construction techniques, including the mining and use of sediments of different colors, the mixing of distinct materials prior to deposition,

and the preparing of submound surface. The rapid yet structurally ordered events at Poverty Point implies a high level of labor investment and social organization, especially for hunter-gatherer peoples, and we suspect that the act of building these earthworks was itself imbued with ritual-religious meaning.

The material culture is one of the most typologically and geographically diverse assemblages in the Eastern Woodlands and points to visitation by people of highly diverse backgrounds. Kidder (2011) and Spivey et al. (2015) hypothesize that the massive construction projects undertaken at Poverty Point after c. 1400 cal. BCE were about creating and recreating a new shared cosmology or cultural narrative to accommodate intensifying social complexities brought on by episodic pilgrimage visits by participants with varied geographic, ethnic, and social origins. Thus, rather than considering Poverty Point as an outsized village different from contemporaries across the Southeast only in size and quantity of imported goods, it is better to consider Poverty Point a religious or ritual center of congregation, what Renfrew (2001) has called a Location of High Devotional Expression akin to Chaco Canyon or Stonehenge.

The idea that Poverty Point is a ritual center is alien in this relatively early North American context, because hunter-gatherers – even complex ones – are not given credit for these behaviors. Traditional models suggest they do not have complex ritual behavior or elaborate religious practices, because they are busy eking out an existence in the face of uncertain circumstances. However, new data from Poverty Point provides an opportunity to reframe the debate from the presumption that economic imperatives must be the sole driver of hunter-gatherer social change. People living at Poverty Point-era sites did not need to trade vast distances to get their basic tool stone. From a wholly utilitarian position, in fact, the idea that people should go hundreds of kilometers out of their way to get raw material – some of which is of dubious quality – is preposterous. We argue instead that economic interactions were trailing behind more ritual-religious processes. Imagining this sort of complexity for Poverty Point may seem extreme, in part because defining why ritual-religious events occurred is exceedingly difficult; the reasons may be wholly idiosyncratic or based on the emergence of prophetic persons or theophanies whose manifestations are archaeologically difficult to recover or even intangible. Christian ritual, after all, is based on miracle births, visions, acts of healing, and apparitions. At this point, proving the cause for the structure of Poverty Point and its associated sites is difficult. However, it is clear that the explanation for the production and reproduction of Poverty Point communities lies in understanding the complex histories of these remarkable sites.

Introduction

Presently, the study of power dynamics and the constitution of knowledge and its multiple connections has a relevant place in social sciences. Much of this discussion is indebted to the work of the French philosopher Michel Foucault (1926–1984). Foucault is frequently defined as a poststructuralist, along with other major references such as Gilles Deleuze, Jean-François Lyotard, and Jacques Derrida. Although he rejected an explicit adscription to this movement, his studies adopted some of its basic ideas (including an interest in discourse and history). Foucault attempted to understand some of the features of modernity, discussing those which were perceived as natural or obvious. He considered that the past was the key to analyze the conditions for the formation and transformation of subjects, objects, and its constituent relationships. He believed that these conditions were necessary to establish a certain regime of truth and social order at a given moment. Foucault developed a critical history of thought, which should not be confused with a history of the ideas.

Archaeology and genealogy were Foucault's particular ways of engaging with the past (Guting 2011). The archaeological method intended to be a critique to traditional history. While the latter approach relied on individual consciousness, Foucault's archaeology insisted that thought was governed by unconscious rules. These rules were present in discourse, in other words, a set of statements that produced knowledge. Foucault intended to recognize different discursive formations in the history of Western civilization. He eventually found out that the modern way of understanding the world was contingent (not an absolute or ultimate truth). The archaeological method did not provide sufficient tools to account for the transformation of discursive formations. Genealogy proved to be a more diachronic tactic (Foucault 1980). It was based on some ideas proposed by the German philosopher Friedrich Nietzsche. And it considered the way in which certain discourses had given way to what constituted the present. In the genealogical analysis, power became a relevant concept (Bapty and Yates 1990).

Key Issues/Current Debates/Future Directions/Examples

Foucault confronted previous understandings of power. The case of Marxism is particularly illustrative. Marxism understood that social classes in the capitalist mode of production were defined by ownership, and that ownership invested the members of a certain class (the capitalists) with power over the rest of society. Power relationships were thus rooted in economy, and politics (mainly the state) served the purpose of protecting the interests of the owners (Shackel 1993). This had a negative impact on the less privileged classes, which were kept under control through mystification and repression. Foucault believed that power was decentered. It was not something that people could either possess or lack. Power "[was] exercised through a net-like organi[z]ation" (Foucault 1980: 98). Every member of society took part in the network, and most people could simultaneously exercise and be the target of power. Discourses and power were inextricably connected, as power was both the product and producer of truth and knowledge.

In the modern world, power discourses were not limited to coercion. They also relied on discipline (Foucault 1975). Discipline was a key concept in Foucault's work. It referred to a wide range of techniques which sought to control people's

actions through time, space, and movement segmentation. Disciplines acted on the material body and generated specific gestures. They had two goals: increase body utility and docility. Disciplinary success depended on surveillance. Surveillance used the gaze as a means to control bodies. Surveillance techniques materialized in space, and panoptical architecture (where people could be watched without knowing exactly when) was an example of that. Information obtained through surveillance encouraged a sanction-gratification system that expected to correct deviations. According to Foucault, discipline participated in the construction of individuals. In this respect, it is important to note that discipline did not act globally. On the contrary, it separated (individuated) people in order to become effective. The construction of individuals relied on an additional factor: the recognition of people's own subjectivity. This went hand in hand with an introspective view, a self-awareness which facilitated the internalization of discourses (as people considered these discourses to have positive effects on their lives).

Foucault argued that discipline sought to create an economy of power (Foucault 1975). Power should be distributed homogeneously, so it was not too disperse or concentrated. Power should be present everywhere in a continuous though subtle way. From a Foucauldian perspective, the analysis of power needed to consider the role of institutions (as they were effective means to distribute power). Modern states helped to control several aspects of life through an ever increasing number of formal institutions. Foucault was famous for his analysis of the disciplinary character of prisons, schools, hospitals, asylums, military organizations, etc. These institutions inculcated norms of behavior, distinguished between the normal and the deviants, and corrected the inclinations of the latter. Some organizations were also important in the consolidation of what Foucault termed biopower: the control of bodies and populations justified on an alleged protection of life. But state institutions were not the only ones that produced and reproduced the knowledge-power discourses of modernity. Other entities, though smaller and less formally regulated, helped in the process. Among them, it is worth mentioning the family, workplaces, etc.

In studying power, Foucault coined the term governmentality. Governmentality involved a conjoint analysis of the government and the particular modes of thought (historical discourses) which were connected to it. In Foucault's work, the government was understood in a broad sense. It did not only include politics and the state but also other realms of social life (for instance, the household). Furthermore, it did not only entail control over other people but also over oneself. Foucault asserted that in the modern world the development of the sovereign state coincided with the birth of the individual (Lemke 2001). The idea of governmentality eventually gathered the technologies of domination and the technologies of the self. Although most of Foucault's studies focused on the first topic, some of his later works considered the importance of the second. In general, the technologies of the self were defined as a series of operations that individuals effected on their bodies and souls with an aim to achieve a certain state (such as happiness) (Foucault 1988).

Archaeology, not necessarily in a Foucauldian sense, but as a discipline deeply concerned with the study of social life and material culture, did not escape Foucault's influence. After what is usually termed the postprocessual or postmodernist turn in archaeology, some scholars became interested in his work (as well as in the work of other social theorists). Although some archaeologists dealing with premodern settings include Foucauldian concepts in their investigations, most researchers citing Foucault are currently interested in the modern world. This is not surprising, as Foucault devoted an important part of his efforts to understand the dynamics of modern society (and its genealogy in Western civilization). Taking this into consideration, it is clear why some of his concepts cannot be easily applied to any historical context. Just to give an example, discipline, panopticism, and individualism cannot be universalized as they are connected to a particular regime of power-knowledge (that of capitalism).

The works of Matthew Johnson and Martin Hall reflect Foucault's relevance in historical

archaeology. Johnson (1996) stressed that historical archaeologists should focus on capitalism, as it was the leading force behind a series of significant changes from the Late Middle Ages onward. Individuality, segmentation, and standardization were key concepts in Johnson's research. These ideas – although not in an explicit manner (Leone 2009) – had several connections with Foucault's understanding of power (its mechanics and outcomes). Martin Hall (2000) insisted that Foucauldian statements could be the building blocks of historical archaeology, as they allowed connecting things (the remains found in archaeological contexts) and words (mainly historical documents). Statements had multiple and changing meanings, giving archaeologists the opportunity to reinterpret the past in the present (and the present through the past). Following Hall, the articulation of statements in discourses (which made social practices regular) was a crucial step in studying the relationship between different scale units. In this way, he thought it was possible to connect local statements and global discourses.

Historical archaeologists also turn to Foucault in order to approach specific problems and case studies. In this context, it is worth mentioning the analysis of etiquette, institutions, the state, etc. The analysis of etiquette frequently considers the role of personal discipline. Just to give an example, Paul Shackel (1993) and Mark Leone (1999) discussed the multiple ways in which institutions and people themselves produced and reproduced certain practices and ideas which encouraged individualism and social difference (mainly in Annapolis and its surroundings). The study of institutions often considers the role of materiality in the construction of power relationships. Panopticism and disciplinary practices thus appear as relevant issues. Lu Ann de Cunzo (2006) made a review on total institutions and asserted that archaeological works on the issue should include prisons, schools, hospitals, almshouses, and workplaces in different geographical contexts. Some other studies focus on state intervention on different aspects of social life and the discipline. Matthew Palus (2011) used the concept of governmentality to understand how the life of citizens was "colonized" and regulated through the material presence of infrastructure. Meanwhile, Palus et al. (2006) referred to different situations where governmentality could explain the control of the archaeological practice (and the restrictions to critical analysis).

Some fields of study (whether or not connected to historical archaeology) accept the theoretical importance of the author. This is the case of postcolonial studies and the archaeologies of gender and the body. Foucault's influence on postcolonial studies was connected to the imprint he made on postcolonial theorists such as Edward Said (Gosden 1999). According to Said, the concepts of discourse and power were relevant to promote a solid critique to the way in which the West traditionally understood the East (and more generally, other cultures). Western discourses (including state and scientific discourses) represented the East as being the contrary to the West (inferior, passive, irrational). These assertions were seen as natural and materialized in a series of actions which ended up in the domination of the East. Gender archaeologies recognized Foucault's impact on third-wave feminism (Gilchrist 1994). In this particular case, the concepts of discourse and power were relevant to discuss the social construction of femininity and masculinity. Finally, the archaeologies of the body insisted that some Foucauldian notions such as discipline, biopower, and biopolitics could be useful to understand the multiple ways in which power and discourses constitute the materiality of our own bodies and gestures (Hamilakis et al. 2002).

It is important to note that although many archaeologists refer to Foucault and highlight the potential of his work, they do not use any of his concepts in dealing with their own research problems. In general, if somebody compares Foucault's influence with that of other social scientists in contemporary archaeology (for instance, of Marx or Bourdieu), he or she will realize that it is minor. Some scholars suggest that this situation is connected with Foucault's limitations to account for resistance and agency (two hot spots in the discipline) (Meskell 1996). Here it is important to make some things clear. First, although Foucault placed much attention on dominance, his netlike conception of power admitted the

possibility of response. Second, his later works opened up an avenue to study individual expression through the concept of "techniques of the self." Third, the work of Foucault can engage in a dialogue with the work of other theorists enriching archaeological analysis. The works of Shackel (1993), Leone (1999), and others are just examples. It would be interesting that in the near future, more and more archaeologists could take advantage of Foucault's insightful ideas.

Practice Theory in Archaeology

Craig N. Cipolla
School of Archaeology and Ancient History, University of Leicester, Leicester, UK

Introduction

Practice theory represents one of the most influential bodies of thought in contemporary anthropological archaeology. First incorporated into archaeological circles with postprocessual critiques of the 1980s (e.g., Hodder 1982), it has remained a hallmark of archaeological theory over the past three decades and continues to inform current debates over agency, identity, and materiality. Although definitions and applications vary

between practitioners, all practice approaches share common interests in action (or agency), context, and history. When considered in terms of the structural-functional and evolutionary frameworks of processual archaeologies, these practice-based foci challenge archaeologists to look beyond large-scale cultural processes to consider the role that individuals played in reproducing their respective social and cultural milieus. At the heart of all practice-based approaches lies a fundamental acknowledgement of the recursivity of social life, an invitation to explore the roles that different social entities – both human and nonhuman – played in reifying, shaping, and even challenging the structures of society. In this entry, I provide basic definitions for practice theory and several other closely related concepts. I trace their historical genesis and impacts in the field of archaeology and outline key issues and debates, including those related to power, agency, identity, cultural interaction, and the dynamism of cultural continuity and change.

Definition

In many ways practice theory defies definition. It is a body of thought first developed in sociology and cultural anthropology. It builds upon Marxist notions of *praxis* – putting ideas and theories into action – and serves as a general critique of both functionalism and structuralism in the social sciences. Yet it lacks the predictive and law-generating components of other theories employed in archaeology (e.g., cultural evolution), resembling a loose collection of possibilities rather than a deterministic and universalized model for how societies and cultures work, persist, and transform across time and space. Those archaeologists influenced by practice theory focus on the recursive ties between individuals and their surroundings – including other individuals, collectivities, and material culture. These interconnections shape individuals' choices, actions, and representations (*practices*). Because they are recursively entangled, however, there is a "duality of structure" (Giddens 1979): social contexts influence practices, just as practices influence the social contexts in which they occur. Practice approaches thus strive to locate and study the roles that individuals, material culture, and other social entities play within processes of cultural reproduction (and transformation). According to the practice theorists discussed below, the things that people do and the representations that they produce are not mindless behavioral responses following broad-scale evolutionary schemes of adaptation nor are they passive reflections of the cultural laws and regulations nested in actors' heads. On the contrary, they are the active, meaningfully constituted loci of social and cultural reproduction, the dynamic and improvised interplay of individuals and their surroundings, and the arenas in which cultural change and continuity take form.

Historical Background

During the 1970s and 1980s anthropologist Pierre Bourdieu and sociologist Anthony Giddens each produced comprehensive theories of practice, both of which proved foundational for all subsequent practice-based approaches (see also de Certeau 1984, Sahlins 1985, and Butler 1993 for examples of other influential theories of practice in the social sciences). Each model focused on the recursive interconnections between individuals and their surroundings, framing practices (or actions) as "prime movers" in processes of social and cultural reproduction. Although Bourdieu and Giddens employed different concepts in their respective theories, each strove to explore the roles that individuals (not just charismatic "Big Men") played in the reification of social structures through time and across space. Ian Hodder and his students at Cambridge later turned to the work of these thinkers in efforts to address issues of action, context, and history via the archaeological record. Such questions had been overlooked or rendered insignificant within the structural-functionalist frameworks of processual archaeology and thus came to play an important part in the emergence of postprocessual archaeology. Twenty years after these initial postprocessual critiques, Timothy Pauketat (2001a)

proposed a move towards *historical processualism*, his term for an integration of processual and postprocessual archaeologies, also rooted firmly in practice theory. I explore each of these innovations below in order to better contextualize the origins and uses of practice in archaeology.

Pierre Bourdieu actually began his career as a structuralist. He conducted ethnographic fieldwork in Algeria among the Kabyle, subsequently publishing his oft-cited description of the organizing principles of opposition inherent in Kabyle households (quoted at length in Bourdieu 1977 and reprinted in Bourdieu 1990). Of note, this analysis first appeared as a chapter in an edited volume dedicated to the work of structuralist Claude Lévi-Strauss. In the initial publication, Bourdieu discussed the sets of homologous oppositions ordering Kabyle households, such as female/male, dark/light, and low/high. Unlike other structuralists of the time that focused primarily on identifying such underlying organizational schemes and treated such patterns as *direct reflections* of the cultural principles stored in people's minds, Bourdieu began to consider the significance of social practices, situated between thoughts and things. In contrast to standard structural approaches, he came to focus on the dynamic and dialectical relationships between objectification (e.g., the physical structure of the Kabyle house) and embodiment (e.g., bodily experience of the house) as a key component of social reproduction. In his own words:

> The house, an *opus operatum*, lends itself to deciphering, but only to a deciphering which does not forget that the "book" from which the children learn their vision of the world is read with the body, in and through the movements and displacements which make the space within which they are enacted as much as they are made by it. (Bourdieu 1977: 90)

Published in French in 1972 and translated to English in 1977, Bourdieu's *Outline of a Theory of Practice* addressed these issues for anthropology and for social theory in general. According to Bourdieu's theory of practice (1977, 1990), cultural reproduction takes place unconsciously in the mundane details of everyday life. These processes operate within the recursive connections between individuals and their surroundings. The things that individuals do and the representations that they produce simultaneously take shape from the practices and representations of others around them while also influencing future practices. Bourdieu (1977: 72) described this feedback loop as follows:

> The structures constitutive of a particular type of environment (e.g. the material conditions of existence characteristic of a class condition) produce *habitus*, systems of durable, transposable *dispositions*, structured structures predisposed to function as structuring structures, that is, as principles of the generation and structuring of practices and representations which can be objectively "regulated" and "regular" without in any way being the product of obedience to rules, objectively adapted to their goals without presupposing a conscious aiming at ends or an express mastery of the operations necessary to attain them and, being all this, collectively orchestrated without being the product of the orchestrating action of a conductor.

For Bourdieu, the stability of social structures and the endurance of societies' schemes of classification and regimes of power are wholly dependent upon an assumed natural order, unquestioned beliefs in the way that things have "always" worked. The arbitrary (and inorganic) nature of certain structures is only brought into focus and questioned when an alternative way of life presents itself, introducing the possibility for practices to become politicized and for social transformation to occur. Bourdieu (1977: 164) used the term *doxa* to refer to this phenomenon. If some component of social life is *doxic*, it is taken to carry no political connotations since there is literally no conceivable alternative way of doing (Silliman 2001: 194). Once questioned and dissolved, doxas are subsequently reestablished through orthodoxy or continually challenged through heterodoxy. Archaeology is particularly well positioned to address issues of doxa given its long-view perspectives on human history (Loren 2001; Silliman 2001, see also Smith 2001 for a critique of doxa in archaeology). For example, archaeologist Stephen Silliman (2001) used this concept to interpret colonial interactions between Native Americans and colonialists in nineteenth-century California. He

framed colonialism and its introduction of novel forms of material culture as a break in the doxa of pre-colonial North American societies.

Bourdieu's theory also rests upon the concept of *habitus*, a term that he appropriated from the work of Marcel Mauss. Recursively linked to its surrounding structures, habitus is an individual's embodied predisposition to act in certain ways. The habitus is a durable *but transposable* set of dispositions amalgamated from a person's life experiences and cultural repertoires, simultaneously structur*ed* and structur*ing*. In Bourdieu's (1977: 78) words:

> The habitus, the durably installed generative principle of regulated improvisations, produces practices which tend to reproduce the regularities immanent in the objective conditions of the production of their generative principle, while adjusting to the demands inscribed as objective potentialities in the situation, as defined by the cognitive and motivating structures making up the habitus.

Although similar in some manners to the concept of culture, habitus adds a degree of fluidity and flexibility to processes of social and cultural reproduction. Habitus is "regulated" and "tends to reproduce" regularities, but it is also improvised and context dependent. In contrast to previous understandings of culture in anthropology, practitioners taking influence from Bourdieu "assume that society and history are not simply sums of ad hoc responses and adaptations to particular stimuli" (Ortner 1984: 148). Practice-based approaches thus acknowledge the ever-present possibility of structural transformation from within.

Sharing many qualities with Bourdieu's theory of practice, sociologist Anthony Giddens' (1979, 1984) theory of *structuration* represents a middle ground between objectivism and subjectivism in the social sciences. On the one hand, Giddens critiqued functionalism and structuralism for their *objectivist* emphases on the social whole over its parts (individuals). On the other hand, he framed hermeneutics and interpretive sociologies as *subjectivist* in their sole focus on the experiences of individuals. Giddens (1984: 2) sought to establish a theory of practice situated between these two extremes, making the basic domain of study in the social sciences "social practices ordered across space and time." Like Bourdieu, he identified practices as the loci of social reproduction by virtue of their recursive connections to systems of social structures. From this perspective, there is a *duality of structure* for Giddens (1979: 5): "structure is both medium and outcome of the reproduction of practices."

In the most basic sense, Giddens (1984: 17) conceptualized structure as the rules and resources that make it possible for similar social practice to exist across spans of time and space. As social practices are reproduced across space-time, they take on increasingly systematic forms. For Giddens (1984: 25):

> Analyzing the structuration of social systems means studying the modes in which such systems, grounded in the knowledgeable activities of situated actors who draw upon rules and resources in the diversity of action contexts, are produced and reproduced in interaction.

According to the theory of structuration, social reproduction occurs as individuals make choices and engage in practices, many of which operate on the level of what Giddens (1984: 6–7) calls *practical consciousness*, a concept sharing several parallels with Bourdieu's ideas of habitus and doxa (see above). This realm of human awareness and belief exists between discursive consciousness – in which people have the ability to explain and express their motivations for acting in a certain way and not another – and unconscious motivations, of which individuals are unaware. Practical consciousness thus encompasses the reasons "behind" all practices that people engage in, of which they are aware, but cannot explain discursively. In other words, as people go about their daily lives, much of the work that they do in recasting social structures takes place beyond the realm of language (including "secondary rationalizations"). Of note, Giddens also recognizes the permeability and context-dependent nature of the divide between practical and discursive forms of consciousness.

With this facet of structuration, Giddens (1984: 9) also offered a broad definition of agency as the capability of doing things: "Agency concerns events of which an individual is the perpetrator, in the sense that the individual could, at any phase

in a given sequence of conduct, have acted differently." This definition overlooks the agency that other theorists like Alfred Gell and Bruno Latour attribute to material culture (discussed further below).

In 1982, Ian Hodder outlined the potential of practice theory for archaeology in his edited volume *Symbolic and Structural Archaeology*. In the introductory chapter, Hodder (1982) proposed a shift towards structuration as a means of critiquing the then-dominant strains of functionalism and structuralism in archaeological theory. He saw structuration as a move towards a contextual and cultural archaeology focused largely on "the role of material culture in the reflexive relationship between the structure of ideas and social strategies" (Hodder 1982: 1). The structural-functional frameworks of the New Archaeology (i.e., processual archaeology) operated on analogies between social and organic life à la Radcliffe-Brown (Hodder 1982: 2–6). These approaches focused heavily upon adaptation and systems theory in efforts to uncover and identify the laws governing cultural processes. According to Hodder, such approaches also operated on universalizing assumptions that change *always* emanated from outside the system (usually in the form of environmental transformations) and that material culture passively reflected the cultural system of which it was a part. Hodder critiqued these emphases on function and utility as inadequate for explaining cultural change, calling attention to the New Archaeology's skewed focus on universalized cultural "laws" over specific historical contexts and its privileging of collectivities over their constituents (e.g., individuals, material culture, space).

Hodder (1982: 7–9) found similar flaws in structuralism, which he again remedied with reference to practice theory. Structuralists fixated upon the codes and rules of culture and society situated in people's heads. They assumed that the regularities of these codes and rules manifested themselves in observable patterns of interrelations in the world like the polarities of the Kabyle household described by Bourdieu. Echoing Bourdieu's critiques, Hodder found structural approaches inadequate due to their lack of a theory of practice, their inability to explain change across space or time, and their disregard for the individuals of which the observed collectivities were comprised. For Hodder, structuration offered a means of challenging the assumed reflective relationships between thoughts and things while acknowledging the ways in which symbols, actions, and materials were meaningfully constituted and active in societies.

In 2001 Timothy Pauketat (2001a) reiterated the importance of practice theory in archaeology by identifying it as the core component of *historical processualism*, what he saw as an emergent paradigm. Pauketat described historical processualism as a reconciliation of processual and postprocessual archaeologies. This new approach shied away from earlier archaeologies' foci on behavior and evolution to consider the importance of context and history via theories of practice (Pauketat 2001a: 73). He framed these new foci in stark contrast to previous generations' interests in behavior and evolution:

> The critical distinction boils down to the fact that behavior (abstract, goal-oriented human activity) is not practice (homologous actions and representations that vary between contexts or events even in the routinized forms – say cooking in pots – seem to remain the same). From a practice perspective, the locus of microscale and macroscale change is people acting out or representing their dispositions in social contexts.

Pauketat reviewed three current approaches in archaeology – neo-Darwinism, cognitive-processualism, and agency theory – in order to demonstrate their shared focus on issues of practice and history. Following thinkers like Bourdieu, Pauketat (2001a: 74) pointed out that practices are loci of change. In contrast to earlier approaches in archaeological theory based upon functionalism and systems theory, cultural practices *are* cultural processes rather than their consequences. Although the term *historical processualism* never fully caught on, practice-based approaches and the cross-fertilization of both processual and postprocessual archaeologies now represent major components of archaeology in the twenty-first century.

Key Issues/Current Debates

In this section I discuss four reoccurring themes studied and debated among archaeologists taking influence from practice theory: (1) power and agency, (2) identity, (3) cultural interaction, and (4) cultural continuity and change.

Issues of *power and agency* loom large in all considerations of practice. Archaeologists often disagree on the potential that actors have to transform the social structures around them. On one extreme are those that see the overarching structures of society – constantly reproduced by the individuals enmeshed within – as rigidly deterministic; these thinkers portray actors as essentially power*less* in relation to the surrounding collectivity or environment. On the other extreme are those that treat actors as all knowing and ever capable of transforming social structures according to their specific intentions and goals (see Joyce and Lopiparo 2005: 366). Although some archaeologists read these extremes (typically the former) in the theories of practice presented by Bourdieu and Giddens (e.g., Hodder and Hutson 2003: 93), most place Bourdieu's recursivity and Giddens' duality of structure on a middle ground, recognizing the inextricable nature of agency and structure (Jones 1997: 89–90). In addition to these theories, a third and surprisingly underutilized model of practice for archaeologists comes from the work of social theorist Michel de Certeau (1984). His concept of *tactics* emphasizes the recursive relationship between individuals and social structures, acknowledging the roles that individuals play in manipulating and shaping the system while still addressing limitations and unintended outcomes of action.

At the heart of each of these approaches lies the issue of agency (Giddens 1984; Dobres and Robb 2000; Joyce and Lopiparo 2005), or the ability of individuals, groups, and even material cultural to act upon and shape society. Archaeologists often use this concept to address the roles that social entities play in processes of cultural continuity and change (discussed further below). It should be noted that agentive action – both a structured structure and a structuring structure from Bourdieu's perspective – has the potential to result in *both* stability and/or transformation. Although Bourdieu, Giddens, and de Certeau each positioned agency within processes of cultural reproduction in a distinct manner than the next, all emphasized the *simultaneity* of structure and agency. On a similar note, Rosemary Joyce and Jeanne Lopiparo (2005: 365) point out the interpretive dangers of treating agency and structure as intermittent, "as an alternation of moments of the exercise of agency in an otherwise continuous flow of structure," rather than as constant and seamless.

The second theme, *social identity*, represents another key area of study in contemporary archaeology. Practice-based approaches often focus on the ways in which individuals and groups construct and negotiate their identities via the material world. For example, Siân Jones (1997) employed Bourdieu's theory of practice in her considerations of ethnic identity and material culture, while Diana DiPaolo Loren (2001) used the concept of doxa in her study of dressing practices and their roles in both French and Native American identity construction within the colonial politics of seventeenth- and eighteenth-century North America.

Similar to the perspectives it offers identity studies, practice theory also sheds new light on the dynamism of *cultural interaction*, particularly in instances of cultural contact and colonialism. For example, Kent Lightfoot, Antoinette Martinez, and Ann Schiff (1998) used a practice-based approach in their analysis of cultural admixture in interethnic households of the Native Alaskan neighborhood at Colony Ross, a nineteenth-century Russian fur-trading settlement in northern California. The neighborhood was composed of households, usually occupied by couples of Native Alaskan men and local Kashaya Pomo women. Lightfoot et al. (1998: 209–15) found that domestic routines of households usually followed Kashaya Pomo traditions, while the overall village structure was based upon traditional Native Alaskan ordering schemes. In this instance, both Kashaya Pomo women and Native Alaskan men reproduced "traditional" forms of their culture, making their interethnic households *hybrid* in nature (see also Silliman 2001 and 2009

for examples of practice-based approaches to colonialism in North America).

The fourth theme, *cultural continuity and change*, connects closely with all of the themes discussed above. Given this theme's centrality in all forms of archaeology, it may represent the most influential and productive application of practice theory in the field. Tim Pauketat (2001b) frames the insights that practice theory sheds on issues of cultural continuity and change in terms of *traditions*. In contrast to earlier generations of archaeologists that treated traditions as conservative and resistant to change, Pauketat (2001b: 2) views traditions as practices brought from the past into the present. Instead of approaching traditions as the constant variables of culture, Pauketat takes a contextual practice-based approach and frames traditions as arenas of cultural transformation. As individuals and groups "replicate" the traditional practices of their ancestors, they always introduce some degree of change (e.g., invoking these traditions in new temporal, spatial, and social contexts). Stephen Silliman (2009) takes this general idea one step further by arguing that cultural continuity and change are inseparable, forever fused to one another within the seamless whole of cultural reproduction.

Future Directions

Although not always directly tied to thinkers like Bourdieu or Giddens, contemporary interests in material culture theory embody the recursive spirit of practice theory. The last 15 years or so represent an important stage for the interdisciplinary study of material culture as evinced by the founding of the *Journal of Material Culture* in 1996 and a recent proliferation of books, journal articles, edited volumes, and conference papers addressing the interconnectedness of material culture and social relations. This trend fostered a notable fluorescence of studies that make use of the term "materiality" in fields as diverse as anthropology, archaeology, design studies, history, human geography, museology, philosophy, and sociology. Most thinkers making use of the term "materiality" are dedicated to moving beyond the dichotomous legacies of the Cartesian divide of mind and body which permeates much of social science, cleaving the material and the immaterial, nature and culture, and the object and the subject. In light of the dialectical (and recursive) pull that exists between people and things, thinkers such as Alfred Gell and Bruno Latour recognize that agency is not limited to humans alone.

Archaeologists following in these directions note that the things they excavate and analyze were deeply embedded in past societies and cultures (or networks à la Latour) in relationships far more complicated than mere reflection. By continuing to recognize that humans and objects are dialectically bound and thus inseparable in terms of social analysis, archaeologists have begun to explore the culturally specific manners in which the material world participates in past social relations. This participation hinges upon the recursive interconnections pointed out in Bourdieu's practice theory, Giddens' theory of structuration, and the many iterations of practice theory employed in contemporary archaeology.

Practices and Techniques of Roman Centuriation

Michele Fasolo
Rome, Italy

Definition

The term centuriation as it is commonly used today describes the practice of the Roman state to divide and allocate agricultural land. Actually, the *centuriatio* is inscribed, along with other rules of ground subdivision within a broader disciplinary scope. The *limitatio* was the technique of delimitating and subdividing space which was achieved by tracing the *limites* or boundaries. Together, these two practices constitute the most characteristic elements of centuriation.

Centuriation consisted mainly of the measurement of public land and its subdivision for the purpose of an agrarian assignment in regular plots (the centuries), usually squares of 20 *actus* (*actus* = an area of 14,400 ft^2) per side and therefore with an area of 200 *iugera* (1 *iugerum* = 2 square *actus* (240 × 120 ft) = 28,800 ft^2 = 0.252 ha); two *iugera* comprised a *heredium* (0.504 ha). The model would have derived its name, *centuria*, originally because the land was assigned to 100 owners to each of whom they assigned a *heredium*, which became private property *optimo iure* (Varro *Res Rusticae* 1, 1, 2; Columella, *Res Rusticae* 5, 1, 2; Fest 53).

The fencing arose from the orthogonal intersection of various dividing lines (*limites*), materialized in various ways on the ground. The *limites* had an amplitude that varied according to their location within the grid and therefore to the role played within the system. Most of them consisted of streets. The lines, with reference to the general orientation of the centuriation, took the name of *cardo* and *decumanus*, respectively. The east-west-oriented *limites* were called *decumani*, those orthogonal to the previous ones were, from the north to the south, called *cardines*. The lines whose tracing on the ground gave origin to the grid were called, respectively, *decumanus maximus* and *cardo maximus*. Both in theory and in practice, this general approach knew many variations.

This redefinition of an agricultural space that made it rationally functional to the political, administrative, and economic activities of a settlement was mostly part of more complex territorial planning operations implying extensive plumbing, deforestation, the creation of a road network, and the establishment or renovation of inhabited towns.

The structural elements of the ancient Roman agrarian structures (networks of roads and canals,

signs of division of land, rows of trees, trees, hedges, ruins, devotional places at intersections) are still recognizable today in various ways on the ground and in the landscape even though there have been many alterations to the original forms (AA.VV. 1983; Talbert 2000). They can be defined as a whole, as Tozzi wrote, "the most impressive archaeological document of Roman civilization" (Tozzi 1974).

The Sources

The sources are numerous and varied. They include textual sources, i.e., inscriptions and literary texts and manuscripts (the writings of the Roman land surveyors), as well as surviving monuments that remain, and the very persistence of ancient cadastral surveys and assets in the landscape itself. The main written sources for the study of the centuriation and of the activities carried out by the Roman land surveyors, the *agrimensores* or *gromatici*, are collected in the *Corpus Agrimensorum Romanorum*. This compilation of Latin texts was probably assembled during the fourth or fifth century E and includes material from earlier periods and contains both legal and technical content. The works are fragmentary, with innumerable textual variants. Some of them contain miniaturistic illustrations, sometimes colored, which demonstrate that the texts were to be used as manuals and, therefore, had to be didactic. The most important manuscripts are the two (*Arcerianus A* and *B*) kept in the Herzog August Bibliothek in Wolfenbüttel and another in the Vatican Libraries (manuscript known as *Palatinus Vaticanus Latinus*).

Until the nineteenth century, there were few scholars who took an interest in the Corpus. Among them was Abbot Gerbert of Aurillac who became Pope Sylvester II. Then in the nineteenth century, F. Blume, K. Lachmann, and A. Rudorff completed an edition that was published in two volumes between 1848 and 1852 under the title *Die Schriften der römischen Feldmesser* and better known as *Gromatici Veteres* (Lachmann 1848). C. Thulin later partially republished these texts in the Teubner series in 1913 (Thulin 1913). Among the most important writings, the collection includes those from Frontinus, generally identified with Sextus Iulius Frontinus, the Balbus treaty titled *Expositio et ratio omnium formarum*, which provides a reliable model of the type of geometric work that surveyors had to learn to do. The collection also hosts writings attributed in the Corpus to the freedman of Caesar Augustus Gaius Julius Hyginus, librarian of the Palatine library (*De limitibus*, *De condicionibus agrorum*, *De generibus controversiarum*), and the work *De condicionibus agrorum* by Siculus Flaccus (perhaps third century CE). To an author identified as Hyginus Gromaticus, to differentiate him from the other Hyginus, the Corpus attributes the writing *De limitibus constituendis*, very important for the knowledge of Roman centuriation, among the clearest in the collection. With the title of *Libri coloniarum*, the Corpus also includes two catalogues of the colonies. In addition to these texts, the collection includes other disparate, sometimes incomplete, works, concerning extracts of laws, quotations from edicts, legal extracts, a treatise (*De sepulchris*) dedicated to places used for burials, various manuals, a treatise on the gemstones, catalogues of land holdings of the imperial period, *Casae*, and concludes with excerpts from the *Originum* of Isidorus Hispalensis concerning the lands and the measurements, weights, and measures and extracted in Latin from the Euclidean geometry (Campbell 2000).

The Illustrations

Only the *Arcerianus A*, the *Palatinus*, and its derivative *Gudianus* contain the complete series of gromatic illustrations, related to many topics in the texts and perhaps already present in the original texts of the surveyors. The miniatures contained in the *Arcerianus* appear to be more accurate and sober and only in some cases are similar to those contained in the *Palatinus*. O.A.W. Dilke classified the illustrations in the following categories: (a) generic detection techniques; (b) detection techniques, which concern orientation; (c) illustrations, which refer to boundary and boundary stones; (d) plants of surrounding cities and lands; (e) drawings of maps;

(f) illustrations of legal definitions; and (g) theoretical instruction (Dilke 1967).

The simplest drawings, the geometric ones, are monochromatic, light brown. In the most elaborate illustrations, the colors that are used seem to respect conventional codifications like those related to the roads for which red or brown is used, sometimes green, or blue or bluish green for water, and light brown, yellow, or gray for buildings with the use of red for roofs.

History of Studies

It was B.G. Niebhur who first outlined a perspective to study Roman centuriation at the beginning of the nineteenth century. According to the German scholar, the study of the texts of the *gromatici* had to go hand in hand with the investigations on the ground. A few years later, Christian Tuxen Falbe, formerly a ship captain and later consul general of Denmark in Tunisia, a keen lover of archaeological studies, while he was performing difficult surveys in the territory of ancient Carthage, noted the presence in the plain of El Mersa of a network of squares of 708 m per side. Falbe correctly identified them as an intervention of Roman agrarian subdivision, and based on the reading of Appian (*Bellum Civile* 1.3.24), he hypothesized a dating of the colony's *limitatio* at the time of Julius Caesar and Augustus.

During the same period, there came an increasing perfection of cartographic science which made it possible to acquire further acquisitions. Other recognitions of Roman centurial structures were in fact made in the first half of the nineteenth century in the Po Valley thanks to the surveys carried out by the Military Geographical Institute of the Austrian General Staff. Pietro Kandler from Trieste, an epigraphic scholar, recognized the centuriation of Pola, Trieste, and Aquileia already in 1848. In 1857, after similar discoveries in Lesina and Zara, he also identified the centuriated *ager* of Padua (Padova). To him we owe the definition of a method of study that enabled the integration of inscriptions, toponyms, excerpts from the works of the *gromatici*, the cartography, and the direct recognition on the ground.

At the end of the nineteenth century, the respected German topographer Schulten made the most important contribution on the centuriation which manages to physically link technical texts, toponymy, and analysis of cartography. It was not until the 1930s that the studies of Plinio Fraccaro furthered advanced this knowledge. To him we owe the first overall representation of the centuriation in Italy that brought our attention to the relevance of the phenomenon of the *limitationes* of northern Italy. A first complete inventory of surviving evidence was prepared.

In the second half of twentieth century, many scholars have made significant advances in the studies using archaeology, aerial photography, remote sensing, and Geographic Information Systems (GIS) (AA.VV. 1983; Castagnoli 1958; Chouquer et al. 1987). Remote sensing has allowed scholars to grasp traces and elements in the landscape not taken into consideration by the process of cartographic abstraction (Bradford 1957; Fasolo 2006; Schmiedt 1989).

The Procedures of Centuriation

The territories conquered, confiscated, or purchased by the Roman state were included in the *ager publicus populi romani* (land owned by the Roman state). One of the major uses of the *ager publicus* was for colonial foundations, the so-called *deductiones*. The colonies (a community of settlers established by the Roman state) that the Romans founded could be of one of two types: Latin or Roman. Among the various characteristics, the Latin colonies had their own laws and the capability to mint coins, but they could not carry out an independent foreign policy, as they had the obligation to supply military contingents to Rome. Roman colonies were instead formed of Roman citizens with full legal rights, and as such they were an integral part of the Roman state. Colonists often were veteran soldiers.

The *ager publicus* could also be granted to private individuals upon the payment of a fee for its usage in cultivation and pasturage. The wealthy Roman and Italic classes availed themselves of this possibility on the wave of conquests

to establish ever-larger farms for the production of goods for the market and export and to develop migratory breeding. This determined the crisis of small peasant property and the proletarianization of the peasantry. Tiberius Gracchus opposed this, in order to recover the arable *ager publicus* occupied by the wealthy private persons beyond the limits permitted by the law and to redistribute it in small lots to the proletarians in an attempt to recreate the social class of the small peasant proprietors from whom soldiers were traditionally drawn. Large areas of central-southern Italy were recovered following this policy through a restructuring process of the land survey.

The *Adsignatio*

In Roman public law, *adsignatio*, the prerogative of the central power, was the institution through which state lands (*publici agri*) of any origin and in whatever condition they found themselves, passed from the dominion of the state to that of private individuals who acquired full ownership of them. Rome could organize the assignees in communities with administrative autonomy (*coloniae*, *municipia*, *praefecturae*) or continue to keep direct administrative links with them (so-called viritane assignments).

The assigned lands became private property *optimo iure*, a *heredium* of which the private individual had the right freely to dispose of it, giving it as an inheritance, dowry or pledge, and the obligation to reveal it in the census.

During Rome's regal period, the king was in charge of the *adsignatio* (Varro, *de re rustica*, 1.10.2; Cicero, *de re publica*, 2.14.26). In the republican period, the prerogative passes to the Roman citizens, *populus romanus* who decide by voting in the popular assemblies (*comitia centuriata*, *comitia tributa*) or in the *plebis* council a law presented by a magistrate who could be the *consul*, the *praetor*, or the *tribunus plebis* and who could in turn act on his own initiative or pushed by the senate or even as it often happened from the third century BCE onward against the will of the senate.

The law, often called agrarian, identified the territory to be assigned, the extent of the intervention, the number of assignees, and the methods of distribution. In the case of colonial assignments, a further law was necessary that established the order of the colony defining the religious, administrative, and building structures (e.g., the *Lex coloniae Genitivae Iuliae* of 44 BCE for the Urso colony in Spain).

Each law foresaw the modalities of execution delegating them to a commission of magistrates of which it established the number. Generally, there was a triad (*tresviri agris dandis adsignandis*), but it could also be comprised of up to 20 members. A time period, biennial, 3-year, or even 5-year deadline was also envisaged, in which the commission had to exhaust its mandate. To carry out its tasks, the commission used surveying technicians. In the late republican period, this type of procedure began to fail, and land distributions were passed without approval by the *comitia* but by simple act of the extraordinary magistrate under the legal authority that had given him exceptional powers and constituents. In the imperial period, the power to dispose them was taken directly by the *princeps*. The sources report a very few data regarding the costs of *adsignationes*.

The Operations

The *limitatio* started on the ground with a ceremony in which, in the presence of the founder of the colony (*conditor*) or a representative of his, the *auspicia* were taken from the *augur*. The gods were invoked to guarantee property rights and relations. If the interpretation that resulted was favorable, the founder gave permission to start the work.

The Orientation

Then the specific technical operations were carried out, the first of which consisted in choosing the orientation to be imposed on the *limitatio*. The theory suggested was to follow astronomically, *secundum coelum*, by tracing the *maximus decumanus* from the east to west (Front., *de limit*. 27, 28, 31. Hyg. Grom., *de limit. const.*, 167; Lachmann 1848). However, in the writings preserved in the *Corpus*, all the cardinal points are taken into consideration. The authors of the

treatises contained in the *Corpus Agrimensorum,* consider as valid reasons to dispense from the theoretical approach of the axes different factors: the opportunity to make the *decumanus maximus* coincide with a great way of communication that innervates the territory or the morphological arrangement of the land that is required to establish the *maximus decumanus* along the main axis of the territory to be assigned, *longitudinem agri secuti* or the presence of the sea or mountains that advised the use of the natural margins that delimited them as a basis for orientation (Hyg. Grom., *de limit. const.*, 170; Lachmann 1848).

As a matter of fact, on the ground, the studies have found the most disparate orientations, imposed by this type of opportunity. In many cases, a determining factor has proven to be the slope of the ground that was taken into account to achieve optimal water flow systems.

The Determination of North

The determination of the north was carried out using a sundial gnomon. One of the possible procedures has been handed down to us by Hyginus Gromaticus. A circle will have been placed on the flat surface of the ground; the *gromaticus* will have placed the gnomon at the center. Then the points of entry and exit of the shadow of the gnomon were noted during the day on the circumference. The two points of intersection were linked with a straight line and then a line was drawn perpendicularly, starting from the middle of the straight line passing through the center of the circumference. This line coincided with the north-south direction. Another version of the same procedure is also reported to us by Vitruvius (Vitruvius, *de architectura* 1.6.6–7).

The Creation of the Squaring

Then the *gromaticus* fixed the orientation, and the point was chosen in which to place the *groma*, *posita auspicaliter* (Hyg. Grom., *de limit. const.*, 170; Lachmann 1848). He then proceeded to originate the grid by tracing two lines that crossed strictly at right angles. The optimal theoretical rule that wanted this point coincided with the center of the *pertica* (the total area of land measured and allocated) and perhaps with the center of the urban structure of the colony in which the territory belonged to (*constituendorum limitum ratio pulcherrima*, Hyg. Grom., *de limit. const.*, 180; Lachmann 1848), but in reality, a series of exceptions occurred due to the presence of natural impediments and obstructions.

The originating axes of the centuriation could coincide with pre-existing road routes or created simultaneously with the operations of territorial planning. The most relevant example is in *Aemilia regio* where the *decumanus maximus* is the Via *Aemilia* and the *cardo maximus* from the various and most important routes that connected the Italian Apennines to the lowlands. There are cases in which the roads are independent from the agrarian arrangements (e.g., the Via *Mediolanum-Ticinum* which does not agree with the centuriation of *Pavia*). Roads were soon abandoned when they were no longer linked to the centuriation.

The Establishment of *Limites*

Once the orientation and the point originating from the place were established, the various parallel straight lines began to materialize on the ground, starting with the *decumanus maximus* and then moving on to the *cardo maximus* and the other boundaries. In this way, a predetermined module was reproduced in the whole area subject to boundaries and subdivision.

The *groma*, an instrument for surveying, was similar to the Greek gnomon. It was planted in the ground so that the center of the cross was plumb with the point chosen as the center of the *pertica*. Then the *groma* was rotated until its two arms coincided with the predetermined orientation. From the plumb line (*perpendiculum*) that hung from one of these two arms, the opposite correspondent was scored and proceeded to insert on the ground along the alignment in succession at regular distances poles (*metae*) until reaching a pre-established length. In the case of the creation of canonical centuries of 20 *actus* per side (2,400 ft or 70,968 m), the *groma* was then transported to this point, and we went on to trace, repeating the process, an orthogonal line perpendicular to the previous one in order to define the second side of the centurial module, which could

be a square or a rectangle. Once the square was completed, rigorous control measures were carried out to avoid the accumulation of errors. To measure distances, ten-foot long intervals called *decempedae* (equal to 10 Roman feet or 2,956 m) were used.

The *limites* were named differently and had different widths. For this reason, the *limites* that fell at every fifth interval were called *quintarii* or *actuarii* with reference to the *actus*, the right of passage, as they were accessible public ways. The *quintarii* constituted a term for the verification of the distances (Hyginus Gromaticus, *de limitibus constituendis*). The other *limites* were called generically linear, consisting of simple boundary lines, but they were known as *subruncivi* in Italy where they were cleaned with the billhook or brush axe (Hyg. Grom., *de limit. const.*, 168; Lachmann 1848). The name of this *limes* literally means weeded. To divide internally the centuries into the single allocation rates were then *limites* called *rigores* or *intercisivi* (literally paths that separate). It is not infrequent that centuries are internally divided into four squares of 50 *iugera* each.

The *limites* were named by numbering them starting from the *decumanus maximus* and from the *cardo maximus*, excluded from the computation, with reference to the quadripartition of the space that the intersection at right angles of the *decumanus maximu*s and the *cardo maximus* determined. That is, compared to the *decumanus maximus*, in the context determined by the general orientation of the centuriation, the space was divided into *pars dextra* or *dextrata* and in left or left pars and compared to the *cardo maximus* in *pars citrata* (or *postica*) behind this and *ultrata* (or *antica*) in front of it. The relative indications were reported with the relative roman numbers together with one of the four possible abbreviations: *DD, Dextra Decumanum, SD, Sinistra Decumanum, KK, Kitra Kardinem, UK,* and *Ultra Kardinem*. These indications were coupled with the centurial coordinates with which each single century was indicated within the system.

The prescriptions provided that only the *decumanus maximus* and the *cardo maximum* as well as the *quintarii* were roads, public, or private for public use. The width of the *limites* (*latitudes*) ranged from 40 ft that a law of the Augustan period foresaw the *decumanus maximus* to the 20 expected for the cardo *maximus* and was reduced to 12 ft for the quintari and eight for the *subruncivi*. Both the *Lex Manilia* and *Lex Ursonensis* recall the *fossae limitales* (man-made ditches) that ran adjacent to the limits.

The Markers and Boundary Stones Used to Demarcate the Fields

After the alignment operations which divided the land were completed, Roman surveyors moved to the laying of the intersections (*in mediis tetrantibus*) of the *limites*, of markers called *termini* (*cippi*) that the *Lex Mamilia* sanctioned as inviolable. The shapes, dimensions, and the materials used were varied. According to the Augustan prescription, they had to be made of flint or other stone of not inferior quality *ex saxo silice aut molari* (Hyginus Gromaticus, *de limit. const.*, 194; Lachmann 1848), and they went to every intersection stuck in the ground for at least two and a half feet remaining out of it for a foot and a half. This Augustan in practice must have been disregarded given the very limited number of stones that has come down to us. It is likely that reference was made to wooden stakes, in oak, juniper, or olive.

The upper base of the *cippus* was engraved with the *decussis*, a cross that reproduced the direction of the *limites*. Each stone also had engraved an indication of the couple of centurial coordinates that identified the position of the stone in space with respect to each axis originating the implant. The most consistent group of *cippi* found is that of the Gracchan period, mostly coming from the *ager Campanus* in south Italy. The laying of the stones took place in the context of particular ceremonies that expressed their sacrosanctity, as boundaries were sacred and honored as divinities. On February 23 of each year, the *Terminalia* took place in honor of the god *Terminus* whose cult was said to go back to the institution founded by King Numa. These boundaries had religious significance, and the displacement of a boundary stone

was considered a sacrilege. In coincidence with the intersections, sometimes the temples called *Compita* could be erected where *Compitalia* was celebrated at the end of December or at the beginning of January.

The Drawing of Lots

The *limitatio* started toward the conclusion with the division of the *centuriae* into lots. The parcels pertaining to each assignee could be located separately in more than one *centuriae* or extend over the course of them. The lots were called *sortes* or *acceptae* because they proceeded to assign them, at least from the Gracchi forward, by drawing lots, with two officials handing down the origin, while maintaining the possibility of receiving a nomination appointment. During the imperial period, the best was reserved for the emperor.

Registration of the Allocation and Drafting of Cadastral Maps

The deed of delivering the lot to the assignee was simultaneously registered in a special ledger. The operations then concluded with the drafting of a cartographic representation of the stacking, a cadastral map, called the shape, and more rarely *typus* or *pertica* or, destined to be authentic in the case of the occurrence of disputes. It was arranged in two copies, one of which was bronze displayed in the colony and a second perhaps in canvas sent to Rome where it was kept in the *Tabularium*. No extant copy of a cadastral map is available to us. The fragments of the maps that were reproduced for tax purposes on marble at a scale of maybe 1:50 *actus* with the partitions of the ancient *Arausio, Colonia Iulia Firma Secundanorum* (Orange in the south of France), in 35 BCE, discovered in the mid-nineteenth century, give us an idea of the original form of these types of documents.

The *Gromatici*

The prominent figures of the subdivision operations were technicians from the nineteenth century generally named *gromatici* or surveyors (Behrends and Capogrossi Colognesi 1992; Dilke 1971). They were specialized in the task of surveying measurement operations. In the Latin lexicon, we find a series of possibilities of more precise definition of the single professional figures that composed the category of the *gromatici* through terms that refer to the activity concretely carried out as well as the instrument mainly used. If *mensor* is the generic measurer, the *finitor* is the one who defines the boundaries (Non., *de comp. doctr.*, 11.24; Plaut., *Poenulus*, 48–49), and the *agrimensor* more intensely measures the cultivable fields. Sources also speak of *metatores* or of workers at the pole, of *decempedatores,* or of those who maneuver the ten-foot long rods and finally of the real *gromatici* or of those who, using the surveyor's surface, performed and directed the fundamental operations of measurement on the ground.

In the imperial period, the term *gromaticus* begins to become more prevalent. The profession becomes a prerogative as indicated by the epigraphic testimonies of the class of freedmen. Whether it was the military or civilians, their cultural and educational cradle was in any case the Roman army camp and in particular genius. Also in the imperial period, the *agrimensores* were framed as officials of the state in special colleges with salaries and training schools. The fundamental subject was cosmology and earth physics, whose knowledge allowed the surveyor to master the orientation on the ground. Hence, the geometry applied to the measurement of distances and areas (Cic., *Tusculan disputations* 1.5). The jurisprudence that allowed the surveyor to extricate himself in the delicate terrain of the juridical condition of the soils and of the controversies that arose there was a secondary matter. In fact, the land surveyor did not carry out arbitrary tasks other than jurisdictional matters limited to disputes concerning the land and always that the matter of contention did not fall outside its own geometric competencies in which case the judgment had to be transferred to the *ius ordinarium*. The classes and passing of exams promoted the student to a professional level with permission to be a surveyor. It was illegal to divide the land

without having obtained such authorization; severe penalties were imposed in the case of counterfeit or unfaithful measurements.

Instruments

In Pompeii, in the workshop of the toolmaker Verus, in 1912, a series of instruments used by the *gromatici*, including *a groma* and a sundial, were found. To these instruments must be added *chorobates*, *libella*, and *dioptra*.

Pragmatism in Archaeological Theory

Dean Saitta
Department of Anthropology, University of Denver, Denver, CO, USA

Introduction

Over the past 25 years, the dual nature of archaeology has been widely recognized and accepted by scholars working within the field. On the one hand, archaeology is a rigorous search for truth about the ancient past. On the other, it is a political dialogue with the present. This accepted fact has been accompanied by a sea change in philosophy and theory. A number of important critiques by scholars located worldwide have moved archaeology away from empiricist and positivist epistemologies to various "realist" alternatives. These alternatives (1) appreciate that knowledge is constructed and produced from particular social standpoints; (2) support, because of standpoint sensitivity, theoretical inquiries into gender, race, class, and other structuring relationships in human life; (3) recognize that, even though empirical reality constrains what we can say about the past, there is still lots of room for interpretation; and (4) incorporate, because of theory's inevitable underdetermination by data, broader criteria of evaluation beyond an interpretation's correspondence with archaeological facts and its logical coherence. The influence of the "postmodern" turn in intellectual life is evident here, but so are influences emanating from many other "post-positivist" philosophies of science.

These philosophical commitments come together in what has been promoted as a *social archaeology* (e.g., contributors to Meskell and Preucel 2004). Social archaeology is focused on how different people inscribe meaning in space and time and, through these processes of inscription, construct themselves. It looks to engage multiple interests in the past, especially those of historically disenfranchised groups. These include all those indigenous and descendant populations marginalized by expanding

capitalism and who have been famously described as "people without history" (Wolf 1982). Social archaeology is thus a more inclusive, democratic practice that appreciates "the multiple entailments of our being-in-the-world" (Meskell and Preucel 2004: 3). This is not simply politics by other means; rather, it is good science. Our ability to grasp and learn from the otherness of the past can be enhanced by an engagement with traditional knowledges. In Bernstein's (1988) words, "it is only by the serious encounter with what is other, different, and alien that we can hope to determine what is idiosyncratic, limited, and partial." While serious engagement with stakeholders located outside the academic realm offers particular frustrations and challenges in reconstructing the past, it nonetheless makes us aware of silences that we have been creating and opens up new research directions. Such engagement is right at home in an archaeology that not only seeks to explain but also emancipate, that is, to foster critical thought about the contemporary human condition in hopes of impelling positive social change (Saitta 2008).

Definition

Pragmatist philosophical principles are especially compatible with, and indeed crucial for advancing, a critical social archaeology. Preucel and Mrozowski (2010: 28) define pragmatism as the "distinctive American philosophy that holds that the meaning of ideas or action can be determined by considering what idea or action it routinely generates, that is to say, its practical consequences." They note that pragmatism has never been, and is not today, a unified approach. There are many debates about what the founders of pragmatism (Charles Sanders Pierce, William James, John Dewey) meant and about the accuracy of various contemporary interpretations (e.g., those of Richard Bernstein and, especially, Richard Rorty). Preucel and Mrozowski briefly review some of the ways that pragmatism has been employed by archaeologists. This entry focuses on the influences of Dewey and Rorty.

John Dewey captures the essence of the approach with his notion that pragmatism turns from the "problems of philosophy" to the "problems of men" (Dewey 1917). That is, it applies itself less toward knowing or "getting things right" (in terms of capturing some final transcendental truth) than toward living or "making things new" (Rorty 1989). For pragmatists, making things new requires that we improve our ability to respond to the views, interests, and concerns of ever larger groups of diverse human beings – to expand the scope of who counts as "one of us" (Rorty 1989).

Thus, pragmatism seamlessly dovetails with the kind of sensibility that equips practitioners for using the *craft* of archaeology (sensu Shanks and McGuire 1996: a "unified practice of hand, heart, mind" and "emotion, need, desire") to address human needs. Pragmatism does so without abandoning time-honored and still useful concepts of truth, experience, and testing. Instead, it reformulates these concepts in a way more sensitive to meeting human need. In so doing it responds more directly – and perhaps more coherently and honestly – to the widespread consensus that archaeological work occurs in a political context, and that we must therefore be aware of how the results of our inquiries are used within that context. A brief summary of core pragmatist philosophical commitments follows.

The first core commitment is to an anti-foundational notion of truth – the idea that there are no fixed, stable grounds on which knowledge claims can be established. Truth is not an accurate reflection of something nonhuman; rather, it is a matter of intersubjective consensus among human beings, one mediated by currently available theories, methods, and data. This notion produces a warrant for aggressively experimenting with theory and method in order to arrive at historical truth. Experimentation is crucial for improving and expanding the conversation between and among interested parties of scientists and citizens. It is the vitality of this conversation that moves archaeology and its constituencies toward the sorts of "usable truths" that can serve human need. So understood, pragmatism moves us in directions other than those stipulated by the earliest commentators on archaeology's social relevance. The "New Archaeology" that burst upon the scene in the 1960s sought to establish such relevance when it explicitly cast archaeology as a

science and argued "it is anthropology or nothing." However, advocates like Ford (1973) still saw the "indiscriminant publication of unverified hunches" as an obstacle to archaeology's ability to serve humanity. Today, liberal production and publication of such hunches is seen as critical for advancing archaeology's explanatory and emancipatory project.

The second core commitment is to the idea that truth claims must be evaluated against a broader notion of experience. Specifically, they must be evaluated in terms of their concrete consequences for life today – for how we want to live as a pluralistic community. Instead of simply asking whether a claim about the past is empirically sufficient in light of available data, pragmatism asks *what difference the claim makes to how we want to live*. What are the implications of theoretical claims from evolutionary archaeology, interpretive archaeology, post-colonial archaeology, or indeed any other current framework for understanding society and history for how we think about, and how we might intervene in, human social life? To what extent does a truth claim expeditiously meet the human needs at stake in, say, reburial or repatriation controversies; that is, to what extent does it facilitate putting human souls to rest and human minds at ease? "Experience," in this view, is relational, interactive, and creative. It acknowledges our status as social and historical beings and thus is self-consciously reflexive. Defining experience in this way means that we must subsume the usual realist "criterial" rationality for judging truth claims (i.e., criteria emphasizing logical coherence and correspondence between theory and data) under something that is still broadly criterial but much more qualitative and humanistic – what Rorty (1989) has termed "fuzzy" rationality.

A third commitment is to a particular notion of "testing," specifically as it relates to the evaluation of truth claims produced by different standpoints, perspectives, and cultural traditions. As noted, especially germane to archaeology these days are those truth claims that divide scientific and various descendant community knowledges of the past, including indigenous, immigrant, working class, and other "folk" knowledges. Many have argued that within archaeology, there is no clear epistemology for uniting descendant community and mainstream scientific understandings of the past. Several scholars have advocated a rethinking of epistemology now that previously disenfranchised groups have places at the table. In contrast to the mainstream scientific view where competing ideas are tested against each other in light of the empirical record, pragmatism stipulates that we test the ideas of other cultures and descendant communities by "weaving" them together with ones we already have (Rorty 1989). Testing is a matter of interweaving and continually reweaving webs of belief so as to increasingly expand and deepen community and, perhaps, create new fields of action. Pragmatism prescribes a "measured relativism" that balances a commitment to evaluation with the parallel belief that cultural pluralism is our best recipe for civil cohesion. Latour (1999: 4) captures the same basic idea with his notion of a "sturdy relativism" in which science allows us to be sure of many things but also seeks to make better connections with the wider social collective. For Latour, this relativism is not one that capitulates to "anything goes" or, in his words, to the "frantic disorderly mob."

The specter of *objectivity* haunts these core philosophical commitments. What does objectivity mean in this context? And do we abandon all hope of attaining it by embracing a pragmatist orientation? The notion of objectivity endorsed by pragmatists, as alluded to above, is one that can be described as *dialectical*. Dialectical objectivity takes a particular stance toward the subjectivity of the knower. Whereas other kinds of objectivity seek either to exclude subjectivity (absolute objectivity) or contain it (disciplinary objectivity), dialectical objectivity adopts a positive attitude toward subjectivity. Subjectivity is seen as indispensable to the constituting of objects, as in fact *necessary* for objectivity. As Heidegger (1927) notes, objects first become known to us through action in the world. Knowing is thus acting, and human acting is always acting in company (Fabian 1994). These arguments close the loop to a concept of "objective truth" as a matter of intersubjective consensus – or solidarity – among human beings, rather than as a

matter of accurate reflection of something nonhuman.

This pragmatist notion of objectivity differs a bit from realist notions that are still widely invoked in contemporary archaeology. Realist objectivity stipulates that there is an independent reality, that alternative accounts map it differently, and that, while hope and bias complicate the picture, systematic exploration of similarity and difference can establish credible knowledge claims and produce more complete understandings of the past. Binford (1982) famously characterized this kind of objectivity as "operational objectivity." This qualified notion of objectivity has been endorsed by archaeologists working across the paradigmatic spectrum. Thus, processual archaeologists have called for a "mitigated objectivity," contextualists a "guarded" or "modified" objectivity, and feminists an "embodied objectivity."

The rub is that such notions of objectivity, no matter how well qualified, still might not be best for regulating a more democratic, inclusive, and critical social archaeology. Pragmatism's commitment to "testing" the beliefs of other cultures by interweaving and continually reweaving them with beliefs that we already have best supports an integrative approach to settling differences between indigenous and scientific knowledges. The navigational guide in these encounters is something fully human – wider, deeper, stronger, and better community – rather than some socially independent object that we seek to accurately represent in theory.

Key Issues/Current Debates

How can a pragmatist archaeology concretely serve this enlargement of community, especially when many public constituencies are still utterly indifferent to whether archaeology exists or not? How can we find some measure of integration in the new, post-colonial world?

One obvious way is through the production of knowledge that takes stock of neglected peoples and histories and that focuses on questions other than the kinds of "origins questions" – about the evolution of humanity, agriculture, and civilization – that have traditionally anchored archaeology's more popular writing. Of interest are questions about the "lived experience" of everyday life – its conditions, variations, rhythms, and disjunctions – with answers developed in such a way that they are accessible to those living peoples having a stake in the interpretations. This ambition is only realizable if those whose lives are affected are directly involved in the research enterprise as partners and collaborators, instead of just subjects or informants. Archaeology has been making good progress in reaching out to these groups. New understandings of the past are being developed by the "subaltern" archaeologies of women and racialized others, and by anti- and post-colonial archaeologies focused on indigenous peoples and their histories.

Efforts to develop a "working class" archaeology in the United States are cut from similar cloth (e.g., Saitta 2007; Shackel 2009). Archaeologies of labor are gaining increasing visibility in the States and catching up with those that have been developed elsewhere. A critical history of early twentieth-century coal miners in southern Colorado (Saitta 2007) is one that has been offered as an antidote to *official* histories of the American West. Official histories – especially in the West – are nationalist, progressive, and triumphal, emphasizing social unity and continuity of the existing social order and its institutions (Bodnar 1992). They gloss over periods of transformation and rupture or spin those ruptures (e.g., the American Civil War) as always having produced a better society, "a more perfect union." Alternatively, critical histories deal with context, transformation, and rupture, addressing both the historical process and different narratives about that process. Both kinds of history often conflict with *vernacular* (Bodnar 1992) histories of the past. Vernacular histories are local histories derived from the first-hand, everyday experience of those people who were directly involved with history's events. They are "passed around the kitchen table," conveying "what social reality feels like rather than what it should be like" (Bodnar 1992: 14). Vernacular histories threaten the sacred and timeless nature of official history, just as critical history threatens vernacular history.

Archaeological work in the American West has produced useful, mutually beneficial dialogue with people steeped in vernacular history, such as trade unionists. The vast majority of these people have never had much use for archaeology, realist, or otherwise. Others in the same unionist company, however, are keenly aware that history is complicated and can be written in a lot of ways, all of them deeply political. The gulf between academic and working class cultures, no matter where it is found around the world, is still palpable. We may or may not need a working class archaeology, but it certainly seems that we need a different way of *justifying* it. A key to narrowing the cultural gulf is to appreciate that sites of industrial and class struggle are part of a living history and long commemorative tradition and often considered sacred ground by descendant communities.

Progress is also being made in coping with the other, arguably more difficult conflicts in archaeological interpretation, such as surround compliance with the United States' Native American Graves Protection and Recovery Act (NAGPRA). These conflicts, especially, beg for pragmatic interventions more attuned to "living" than "knowing." By law, NAGPRA compliance is governed by a realist, criterial rationality. The success of a claim for cultural affiliation depends on whether it is supported by most of the available biological, linguistic, archaeological, and documentary evidence. In this scheme native oral traditions are assigned an evidentiary status equal to other kinds of scientific evidence. However, NAGPRA's "preponderance of evidence" criterion remains deeply problematic, both because of the elastic nature of evidence in archaeology (resulting from the particular quality of archaeological data combined with the fact that such data only become "evidence" in light of theory) and because of the often deep contentiousness of tribal oral traditions.

Given this situation, a realist, criterial rationality may not be the most appropriate or productive. Instead, we might follow the lead of those pragmatist philosophers and Native Americans who suggest that a more important and relevant criterion is the consequences of knowledge claims for everyday life: for how we want to live, and for the building of a genuinely pluralist community characterized by mutual understanding and respect. In the American Southwest, for example, Pueblo Indian tribal representatives implicitly endorse pragmatist evaluative criteria where they argue, in so many words, that history is less important than survival and the maintenance of harmonious relationships among the tribes. Survival is understood broadly as political, economic, *and* cultural. Naranjo (1996: 249) takes such a stand where she asserts that, in her view, the Pueblo Indian's primary concern is with "the larger issues of ¼ breathing and dying," rather than with the specific details of knowing that focus scientific world views. This concern for the present as well as the past – for living as well as knowing – represents a significant convergence between pragmatist and tribal epistemologies that is worth exploiting for its unifying potential. But this unity can only be established if we are willing to rethink the usual scientific criteria – that is, empirical and logical sufficiency – for judging and integrating knowledge claims.

Other convergences are apparent in the realm of methodology. Speaking at a conference dedicated to the topic of "Indigenous People and Archaeology," Lomaomvaya and Ferguson (2003) note that:

> In Hopi culture, what stands the test of time is substantive information about the past. Collection and analysis of data requires theory, but for Hopi it is the Hopi past itself that is most important, not what we think this past means for the world beyond Hopi.

This primary interest in archaeological "thick description" of a particular past converges with the pragmatist belief that human solidarity is best achieved not by those disciplines – theology, science, and philosophy – charged with "penetrating behind the many private appearances to the one general common reality" but rather by those which sensitize humans to the experience of diverse "others" through exploration of the private and idiosyncratic. Rorty (1989: 94) notes that "novels and ethnographies" are especially well suited to building this kind of solidarity.

Archaeological narratives attuned to human cultural variability across space and time, and developed via more reflexive and hermeneutic methodologies, can be just as useful.

Despite its critique of criterial rationality and preference for "thick description" over nomothetics, the pragmatist alternative need not be anti-science. This is a perennial criticism of scholars involved in building a critical archaeology. In the pragmatist view, and all things being equal, science is an excellent model of human community and solidarity (Rorty 1989: 15). But, unfortunately, all things are rarely equal. Where compromises are required, it is science that must lead the way, since it has for too long (and as a consequence of unequal power relationships in society) dominated and silenced other ways of knowing. In his *Federalist Paper No. 10*, the American founder James Madison noted the threat to community presented by "majority factions." For Madison, the best corrective to the majoritarian threat was enlarging the scope of community, that is, the number of interests represented at the table of democracy. To the extent that mainstream, realist science is a majority faction in American archaeology, it poses the greatest threat to the project of reconciling competing knowledges and expanding community. Archaeologists and subaltern "others" alike tend to cringe at any call for compromise in the service of reconciliation and stronger community. But Rorty (1998: 52) provides some comfort when he reminds us that, in democratic societies, "you often get things done by compromising principles in order to form alliances with groups about whom you have grave doubts."

Future Directions

Pragmatism emphasizes ways of living instead of rules for knowing, the "weaving together" of knowledges instead of their "validation against" experience, and the social utility of narratives instead of the absolute truth of laws and theories. These governing ideals neither forsake reality nor undermine the possibilities for learning, nor capitulate to relativism in the way that term is usually understood. Pragmatism subsumes Enlightenment criterial rationality and nomothetics to more humanistic – but no less explicit and compelling – regulative ideals. In so doing, it converges with the epistemologies of subaltern groups – native peoples and working classes – for whom the social causes and consequences of scientific knowledge claims can be of great concern. This in turn promises a more collaborative and democratic, and less authoritarian, archaeology.

At the same time, pragmatism usefully breaks with both the analytical (empiricist, positivist) and continental (post-positivist) philosophical traditions that so many around the world have found wanting as underpinnings for contemporary archaeological practice. The desirable outcome of pragmatism's advocacy of these particular notions of truth, experience, and testing is stronger community – richer and better human activity – rather than some singular, final truth about the past or some imagined "more comprehensive" or "more complete" account of history. The loyalty in pragmatism is to other human beings struggling to cope rather than to the realist hope of getting things right; the desire is for *solidarity* rather than *objectivity.*

Pragmatist philosophy is thus fully compatible with the theoretical interests of an archaeology of collective action. It also meets those criteria enunciated by scholars seeking a more *ethical* practice (e.g., contributors to Lynott and Wylie 2000). These include the need to be self-conscious of one's subjectivity, accountable for one's presuppositions and claims, and responsive to the various constituencies having an interest in the past. Pragmatism's ethical imperatives dovetail especially nicely with archaeologies of civic engagement and those that employ "service learning" as a pedagogical tool (e.g., Nassaney 2004) whereby we, as contributors to public knowledge, use our knowledge to serve the public good – whatever we take "public good" to mean.

Whether these ethical principles are best theorized as universal (good for all times and places) or situational (a matter of comparing time and

space-bound practices with each other) is subject to debate. Rorty's (2001) position that community-building is best served by situationalism or, in his terms, "ethnocentrism" is particularly useful: that there is more to be gained by replacing the Enlightenment rationalist commitment to universal moral obligations with the rather more modest idea that we – as Westerners, intellectuals, archaeologists, or whatever – merely have some instructive and possibly persuasive stories to tell that might help to build trust across the boundaries that divide us from others. On this view, moral and ethical progress is viewed as an expansion in the number of people among whom unforced agreement can be established through free and open encounters (Rorty 1991).

Pragmatism's emphasis on narrative and conversation is perhaps its greatest gift to a discipline like archaeology. Indeed, these commitments fit well with those who see archaeology today – given the diversity of theories, methods, and voices that have come to characterize it – as less a well-defined, bounded discipline than a fluid set of negotiated interactions, as less a "thing" than a "process." This "community of discourses" (Hodder 2001), while threatening what some might see as an unproductive dispersion of scientific energy, is mostly to the good if it stimulates imagination and experimentation, sustains intellectual vitality, and produces better understandings of the past as well as better and stronger community.

Prehistoric Human Footprint Sites

Matthew R. Bennett
Bournemouth University, Poole, UK

Introduction

Human footprints were once thought to be rare in the geological record, freak occurrences of sedimentary preservation (Fig. 1). This has changed over recent years with a plethora of discoveries (Bennett and Morse 2014). To give a flavor in 2016, we saw the publication (Masao et al. 2016) of additional footprints at the famous 3.66 million year old footprint site at Laetoli in northern Tanzania first reported in 1979 by Leakey and Hey (1979). Gierliński et al. (2017) reported some potential hominin tracks even older at 5.7 million years old on the island of Crete. There has been new data and interpretations (Hatala et al. 2016; Roach et al. 2016) emerging from the 1.5 million year tracks at Ileret in northern Kenya first reported by Bennett et al. (2009). On the shores of Lake Natron, a late Pleistocene footprint site has been reported with hundreds of visible tracks (Balashova et al. 2016; Liutkus-Pierce et al. 2016). In 2018, the publication of children's footprints in association with butchered hippo carcasses was reported from Ethiopia (Altamura et al. 2018), and there are reports of human tracks in association with giant ground sloth in North

(**g**) Child footprint with preservation of the forefoot and toe pads only

P

America (Bustos et al. 2018). Footprints preserved in peat have been found on the Pacific Coast of Canada (McLaren et al. 2018), and a new footprint site in South Africa is reported by Helm et al. (2018).

This surge of discoveries is perhaps not surprising when you consider just how many footprints the average person makes in their life. Today the average moderately active person takes around 7500 steps a day, and if maintained over a lifetime of 80 years, then they will have left the order of 216,262,500 steps with each step having a potential for preservation. Contrast this with the 206 bones in the human body, and it is not surprising that we frequently uncover fossil footprints.

Issues of Preservation and Analysis

Footprint sites can be classified in a variety of ways but tend to fall into one of two broad types:

Congregation sites occur where humans, and/or other animals, gather at a focal point within a cave, around a source of shelter, or more commonly around a water source. Here, the print density is often high with a large amount of overprinting and taphonomic modification of prints and with intimate association of human and animal footprints. Footprint trackways are relatively rare and when present tend to be short in length.

Transit sites occur where humans, and/or other animals, are moving across a surface forming well-defined trails. It is often easier to make biomechanical inferences at such sites since the trackways tend to be longer and the density of prints and associated overprinting is often lower, although the number of prints can often be relatively small such as the case at Laetoli.

Footprints are preserved in any soft-sediment environment but are typically found in low-energy depositional environments where there is (1) rapid still water sedimentation post-imprinting, for example, caused by the transgression of turbid lake/sea water, or low-velocity flood waters; (2) rapid cementation by fine-grained debris/mud flows such as lahars or fine-grained ash flows; (3) pulses of airborne ash fall; (4) rapid post-imprinting lithification of sediment via desiccation and/or salt cementation of silt/clay, as well as the chemical cementation of volcanic ash; and (5) avalanching and/or settling of dry aeolian sediment. Greater knowledge and exploration of these types of environments within the depositional record will increase the number of known human footprint sites as illustrated in the discoveries of recent years. While tracks may be preserved in a wide variety of sedimentary environments, molding of fine anatomical detail tends to be favored by fine-grained substrates (Fig. 1), which need to be sufficiently dry to have the necessary bearing capacity to hold the weight of the individual print maker and sufficient strength so that they do not collapse as the foot is withdrawn. This is often favored by thinly bedded muds and fine sands which provide a relatively firm, free-draining substrate, but with good molding properties. The typology of footprints varies with substrate moisture content within fine-grained sediments as shown in Fig. 2.

The traditional method of preservation and analysis involve the description of individual tracks and casting with either plaster or more commonly some form of resin. Manual photogrammetry was used at Laetoli (Leakey and Harris 1987), a process which has now been revolutionized by digital photogrammetry (Falkingham 2012; Bennett and Budka 2018). There is an increasing range of sophisticated analytical tools available to examine this three-dimensional data. Not least of which are methods of "whole foot" analysis which allow mean footprints to be determined from trails, allowing more objective hypothesis testing (Belvedere et al. 2018; Bennett and Budka 2018). For example, Fig. 3 shows a mean print of a 14-print Holocene trackway from Walvis Bay in Namibia. The individual prints show considerable typological variation due to subtle variations in substrate properties, but by examining the mean, one is able to remove this noise and make anatomical and biomechanical

Prehistoric Human Footprint Sites, Fig. 2 Model of the typological variation in footprints with changes in substrate properties

Prehistoric Human Footprint Sites, Fig. 3 Illustration of the typological variation in human footprints within a single trail due to variation in substrate. Using a "whole foot" analytical approach, it is possible to calculate a mean and standard deviation for this trail

P

inferences with a greater degree of certainty. This approach has been successfully applied to the Lateoli prints recently (Crompton et al. 2012; Bennett et al. 2016).

Inferences from Tracks

Fossil footprints can provide evidence of (1) human presence at a point in space and time; (2) they can provide us with biomechanical information about the track-maker, for example, comparing the locomotive behavior of *Homo sapiens* with earlier hominins; (3) they can provide kinematic information about speed and style of locomotion (e.g., running versus walking); (4) ecological information where nonhuman tracks are present; and (5) they can tell us about behavior ecology and the interaction of one track-maker with another. Fossil footprints can provide evidence of (1) human presence at a point in space and time; (2) they can provide us with biomechanical information about the track-maker, for example, comparing the locomotive behavior of *Homo sapiens* with earlier hominins; (3) they can provide ecological information where nonhuman tracks are present; and (4) they can tell us about behavior ecology and the interaction of one track-maker with another.

Whatever analytical approach is used, footprints and trails can be used to infer a range of information about the print maker. In Morton's (1935), seminal work on the human foot, he established a basic anatomical ratio of foot length to stature or approximately 15% (1:15). This has been refined into a range of empirical relationships which link foot length to subject height and weight (e.g., Webb et al. 2006; Bennett and Morse 2014). While these relationships provide an approximation for *Homo sapiens*, their applicability to our earlier ancestors is debatable. Inferences on walking speed can be made from step and stride length in trails given an estimate of a subjects leg length (Alexander 1984), although these are again limited by the availability of such information or the assumptions made in deriving plausible input data for extinct hominins. Human footprints also commonly occur in association with animal prints, providing information about the ecological community in which our ancestors lived, although issues of substrate sampling may bias the nature of this record (Falkingham et al. 2011).

In summary, human footprints are preserved in a variety of depositional settings and have much to offer both the archaeological and paleoanthropological community. The foot is a complex structure of 22 bones held in place by a lattice of soft tissue. It interfaces with the ground to create pressures which decelerate, balance, and accelerate the body during walking and running. Human footprints provide a record of these forces, a record of "fossilized motion," and a record of the forces our forebears applied to the ground to balance and propel their bodies.

Prehistory of Southern Central America

Alexander Geurds
Institute of Archaeology, University of Oxford, Oxford, Oxfordshire, UK
Faculty of Archaeology, Leiden University, Leiden, The Netherlands

State of Knowledge and Current Debates

Introduction

The definition of southern Central America used here includes the territory of Panama, Costa Rica, Nicaragua, Honduras, and (eastern) El Salvador while making brief mention of Colombia. Central America typically also includes Guatemala, Belize, and the western part of El Salvador, but the archaeology of these territories is tied more strongly to discussions on the Mesoamerican culture area. The prehistory of southern Central America comprises the Terminal Pleistocene and the Holocene period, from initial peopling of the region up to the period of European colonization in the first half of the sixteenth century. With some frequency, the region is defined as a corridor for human, animal, and plant dispersal. For the earliest Paleoindian period (11500–10,000 BP), the preceramic period (10000–4000 BP), as well as more recent prehistoric times, southern Central America is considered a key area for understanding human mobility, environmental adaptation, and long-distance exchange in the Americas and indeed from a global archaeology perspective.

With the exception of multidisciplinary work in Panama between archaeology and paleoecology, the Paleoindian period is lacking robust chronological control throughout much of the region, the principal exception being central Panama. The long process of plant domestication was introduced, altering the overall vegetation, and around 4000 BP horticultural and agricultural practices were beginning to define the landscapes of both Pacific and Caribbean Central America. During the first decade of the sixteenth century, Spanish colonizers arrived on the Caribbean coast of Panama, going across the continental divide to reach the Pacific and quickly moving northward via the Pacific coast, thereby abruptly ending the prehistoric developmental trajectory, although some indications point to the effective continuation of indigenous lifeways over various decades before the impact of Spanish colonization becomes visible archaeologically. The first half of the sixteenth century left indigenous societies decimated in size and forced surviving groups to seek refuge in difficult to penetrate interior mountainous and tropical forest regions.

The region lacks a singular unifying macroregional narrative, partly due to an overall geography that is varied in nature, caused by a complex geological history including volcanism and active tectonic conditions on the Pacific coast. On the whole, geographical contrasts are somewhat more pronounced in Honduras, Nicaragua, and northern Costa Rica than is the case for central and eastern Panama. Most poignantly, southern Central America is described as a mixture of isthmian and insular forms of landscapes (Cooke 2005).

The prehistory of southern Central America is marked by a history of definitional debates on external and internal spatial boundaries, predominantly in relation to its position to Mesoamerica and parts of northwestern South America. Until recently, the overall area nomenclature was subject to change, with earlier literature invoking area concepts such as "Lower Central America" and "Intermediate Area." Apart from some of these area container concepts receiving critique for their essentially negative definition (Sheets 1992), others only outline those parts of Central America not deemed to show Mesoamerican traits, such as the "Chibchan tradition" (Kirchhoff 1943) or the "Isthmo-Colombian Area" (Hoopes and Fonseca 2003). It's fair to say that this debate is not concluded, with current interpretive emphases shifting to socially informed network perspectives over culture areal discussions. For this entry, the definition of southern Central America is principally geographical and in acknowledgment of the heuristically complex relation to the Mesoamerican culture area. It includes brief references to parts of Mesoamerica,

as well as encompassing those societies displaying forms of relatedness further south, into northwestern Colombia, extending into western Venezuela.

Area Definition

Spatial boundaries recognized in archaeology are always conditioned by time and tend to be uninformative for archaeological reconstructions of prehistoric life, making their definition inherently problematic. Similar problems are encountered in the choice of terms for these regions, all of which carry their own set of implied comparative assumptions. Lastly, when southern Central American subareas are defined, then it is generally only for materials and cultural patterns from 500 BC and later, with an emphasis from AD 600 to 1500, when sociopolitical formations develop and material culture further diversifies in southern Central America. Despite Spanish reports discussing political landscapes in considerable detail, they are difficult to observe archaeologically in southern Central America for most periods, including the last centuries before the Spanish colonization, with exceptions in central Panama and Caribbean Costa Rica.

The northwestern edges of southern Central America are defined by periods of frequent interaction with the southern extension of Mesoamerica. This includes the Maya region, marked by the linguistic spread of Mayan languages into western Honduras and El Salvador, in combination with the presence of stone carved hieroglyphs from about AD 250. This zone is geographically defined to run along the central valleys of Honduras, geologically formed by the Comayagua graben, trending north-south through the country. On the Pacific side, in eastern El Salvador, the regional dynamics are more complex to the point of becoming unclear. Eastern El Salvador, covering about one-third of the national territory, is formed by the course of the Lempa River (Longyear 1966), and this region, together with the adjacent Gulf of Fonseca, presents varied cultural characteristics through time, featuring both localized and Mesoamerican elements. More recent discussions frame this lack of clear patterning as indications of periodic links across cultural boundaries (Sampeck 2014). Following the Pacific coast further south, Greater Nicoya includes the Pacific regions of Nicaragua and the Nicoya peninsula of Costa Rica and was defined originally as a cultural subarea of Mesoamerica, emerging around AD 800, although discussions on this regional perspective are now relying less on historical references to human migratory movements and pushing for more critical and localized archaeological understandings of Greater Nicoya (McCafferty et al. 2012). Greater Nicoya is more clearly supported by archaeological evidence in Pacific Nicaragua and Nicoya, than it currently is for the wider tri-national area around the Gulf of Fonseca.

The southern extremity of southern Central America is particularly challenging to address, as numerous historically deep linguistic and genetic ties exist with parts of contemporary northwest and Caribbean Colombia, and interaction networks were likely frequent and long term, especially from AD 0 onward. A strong ecological continuity between eastern Panama and the Colombian Chocó region as well as around the Gulf of Urabá into the Caribbean plains further strengthens such a hypothesis. Cultural exchanges with parts of Colombia are amplified further by a comparable semiotic corpus materialized in classes of objects, prominently including decorated pottery, metal objects, ground stone sculpture, particular forms of green stone pendants, as well as practices of shell carving. Such exchange and transfer of ideas and practices eventually connected the most northerly stretches of the Andes, the Sierra Nevada de Santa Marta, to parts of Panama and Costa Rica, even though objects chemically sourced to have traversed such distances remain scarce as a result of the lack of analysis. Beyond this, comparisons have also been drawn between the sculptural practices of southern Central American and those of the Cauca Valley in southern Colombia. In short, there is no agreement on where to draw a southern boundary for the prehistory of southern Central America, even if only for heuristic purpose, but it is likely that this boundary not to be sought in Panama but in fact somewhere in northwest South America.

Overall, southern Central America is defined by starkly contrasting geographies, consisting of a combination of tropical highlands and lowlands, each having their own climate and vegetative characteristics (Coates and Obando 1996). Trade winds pushing weather systems into eastern parts of southern Central America influence this geography, leading to more temperate zones on the Pacific side and at times featuring a transitional central highland zone as a third major geographical component. As such the geographical contrast extends to form quite divergent climates on the Caribbean and Pacific coast; the former featuring moist rainforests and the latter defined by drier conditions and a less pronounced hydrology. In Nicaragua, this contrast is influenced by the two large freshwater lakes, geologically formed by the Nicaraguan depression. The larger of the two, Lake Cocibolca (or Lake Nicaragua), drains into the Caribbean Sea by way of the San Juan River, thereby forming the only straightforward connection between Pacific Nicaragua and the Caribbean. In the low-lying grasslands where the lakes are situated, a front arc of active stratovolcanoes is a further main geographical feature. With numerous historically recorded eruptions, this volcanism played a crucial role in later prehistoric periods as well, resulting in abrupt shifts in, for example, settlement pattern and pottery technology. The presence of the two freshwater lakes and the fertile soils generated by the volcanic ash deposits presented favorable conditions in Pacific Nicaragua for early prehistoric settlement.

The eastern region of Honduras, extending northeast of the capital Tegucigalpa toward the Caribbean coastline, comprises an expansive zone of tropical forest, the largest surviving continuous one in Central America today. Rugged terrain and high precipitation make for a challenging environment for archaeological research, and accordingly regional data resolution is still unsatisfactory. The eastern portion of Honduras, crossing the Nicaragua and Honduras border along the Caribbean Sea, is referred to as *La Mosquitia.* This region of grassy savannas, pine forests, marshes, and tidal lagoons is ecologically similar to the Caribbean coastline of Nicaragua. The extensive river deltas and shallow offshore waters that mark this Miskito or Mosquito Coast in Nicaragua are at the root of the isolation these coastal regions have experienced, being largely cut off from the interior regions of Nicaragua and its Pacific coast. In central regions of Nicaragua, there are some archaeological indications of periodic exploitation of Caribbean maritime resources.

The remoteness of the Nicaraguan Caribbean was a likely determinant of regional interaction in prehistory, as it was during Colonial times and in part still is today. These Caribbean coasts run south to eastern Panama, cut by the estuaries of a few major rivers such as the San Juan and the Reventazón River in Costa Rica. Horticultural activities in the Caribbean probably took the form of small gardens near houses, planted with species with an array of purposes. Cultivated flora included plants known for medicinal qualities and those suitable for construction purposes. There are also early historical Spanish references to plantations of peach-palm trees. Finally, in southern Costa Rica, the Caribbean coast is defined by lowland plains where the terrains narrow, giving way to the highlands of the Cordillera de Talamanca that approach the Caribbean coast toward the border with Panama. The Caribbean regions of eastern Honduras, Nicaragua, and Costa Rica are often compared and presented in a joint analysis, sometimes highlighting their "wedged" position alongside the Pacific and central regions, but considerable linguistic and style differences were also present.

Archaeological studies generally focus on sites or natural units of analysis in either the Caribbean lowlands, the Pacific coast, or central valleys or plateaus at somewhat higher elevations. The geography generally facilitates human mobility parallel to the coastlines, and specific cultural and linguistic clustering from AD 600 to 800 onward seems to be loosely correlated to such geographies. That said, the cultural links in the geographically diverse south of Costa Rica and west of Panama provide a counterexample. One element that is a prominent feature in Central America is the range of active volcanoes running from Guatemala all the way into western Panama, interrupted only by the mostly metamorphic

Cordillera de Talamanca. Beyond the numerous prehistoric and recorded historic eruptions, volcanism, and the tectonics underlying their existence, has given rise to highlands, lakes, and extensive lands covered by ash lenses, creating fertile grounds along the Pacific coasts. Alongside the effects on prehistoric subsistence strategies (Sheets and McKee 1994), the highly visible presence of volcanoes is also discussed in terms of how they are rendered in prehistoric indigenous interpretive landscapes.

Southern Costa Rica and western Panama include the Osa Peninsula, and it encompasses the Diquís valley as well as the provinces of Chiriquí and Bocas del Toro. Many river valleys and plains characterize this region, creating a fragmented topography. This nowadays bi-national subarea of Greater Chiriquí is generally treated as a single archaeological unit of analysis, given the already mentioned significant overlap in prehistoric practices and styles visible between them. The Cordillera de Talamanca mountain range separates this region from the Caribbean coast, but there are archaeological indications of comparable cultural developments between the Pacific and Caribbean. Further east, the central provinces of Panama are marked by a combination of stretches of savannas as well as tropical forest zones, a narrow central mountain range of reaching to some 200 meters above sea level, broad coastal bays, and the central lowland zone of the Panama Canal. The distance between Caribbean Sea and Pacific is at times as little as 70 kilometers here. Various rivers discharge into the Pacific Ocean here, creating wide deltas, and in the Gulf of Panama, a number of islands are found that potentially played a role in shell trade along the Pacific littoral. Interestingly, islands are otherwise fairly scarce along the coasts of Central America. Of note are those in the Gulf of Fonseca, in the Gulf of Nicoya, a small spread off the Pacific coast of Chiriquí, the San Blas Islands of Caribbean Panama, and the Pearl Islands of the Pacific Panama. When archaeologically investigated, all exhibited traces of prehistoric habitation or exploitation of maritime resources. This nearshore prehistoric activity is a defining feature for the prehistory of southern Central America, as it features a relatively high coastline-to-land area ratio.

Finally, the eastern third of Panama encompasses the Darien, a region about which systematic regional archaeological knowledge is still very limited, apart from a handful of studies and recent paleoecological investigations. It is a densely forested region, enveloping the entire land area from the Caribbean to the Pacific coast, with hills of modest height near the Caribbean coast, creating wider plains on the Pacific than elsewhere in Panama and covered with subtropical forests. This vegetation is, as mentioned earlier, comparable to the Chocó region environment across the Colombian border. Similar to other examples in southern Central America, here also, contemporary nation state borders complicate regional analysis.

Scholarly Background

Through a combination of historical circumstances and an aesthetically pleasing material culture, the beginnings of systematic archaeology in southern Central America coincide with some of the earliest archaeological studies in the Americas. Historical reasons for this were both US and European economic exploitation in southern Central America through banana and coffee plantations alongside the extraction of various precious metals, further amplified by the establishment of railroads across difficult terrain and repeated efforts to establish a transcontinental canal (initially proposed for Nicaragua, and later for central Panama). These nineteenth- and early twentieth-century conditions resulted in a substantial presence of foreign cartographers, engineers, and travelers, observing on the archaeological remains they encountered. During the first three decades of the twentieth century, a small number of studies were undertaken to explore the indigenous prehistory based on museum collections and field research aimed at assembling archaeological, linguistic, and ethnographic observations. In terms of field archaeology, Carl Hartman's early work on a number of monumental sites in Caribbean and Pacific Costa Rica stands out for its meticulous approach and reporting in this early period of research (e.g.,

Hartman 1901, 1907). Ironically, these early studies were followed by a long period of relative paucity of advancements in the understanding of prehistoric developments, while neighboring regions, prominently Mesoamerica, saw a stark increase in the volume of field projects and overall academic study.

During the second half of the twentieth century, national archaeologies gradually developed, though not necessarily in a comparable way throughout southern Central America. In this same period, from the 1950s onward, a number of archaeological studies followed by scholars based in the USA and Europe. Central to this renewed investigative focus were the argued links between parts of Mesoamerica and coastal South America. Such links, fundamental under the proposed notion of "Nuclear America" (Willey 1955), naturally called for viewing southern Central America as a developmental "axis" between parts of Mexico and its links to the central Andes of Ecuador and Peru. Consequently, a number of archaeological surveying and test excavations were set up along the Pacific coast (overview in Healy 1980). One of the results of research in this period is the observation that earlier indigenous societies on the Pacific coast of Nicaragua and northwest Costa Rica showed Central American characteristics, whereas during later periods, a Mesoamerican influence becomes noticeable. Primarily, these projects obtained a set of markers for macro-regional spatiotemporal control, in many cases the first of its kind in the respective parts of southern Central America.

Later work, during the later 1960s and 1970s, continued to build on existing chronological sequences, expanding on the knowledge of ceramic styles and also outlining regional subsistence strategies and settlement patterns in both the Pacific and Caribbean sides of southern Central America. During this period, the first synthetic publications began to appear, some contained in handbooks, or as monographs (Baudez 1970; Stone 1972), others as standalone articles, such as Olga Linares's still remarkably fresh views (Linares 1979). Studies also sought to address the question of the nature of crop domestication and dispersal and the transfer of particular technologies such as metallurgy across the Americas.

By the 1980s, archaeological research was beginning to grow more substantially, but this was per Central American country highly dependent on political development, causing, for example, a marked difference in research activity between the stable democracy of Costa Rica and the civil war-torn conditions of Nicaragua and El Salvador. In Panama, the establishment of the Smithsonian Tropical Research Institute in 1966 (with historical roots in the Panama Canal project) provided a major push in studies on human-environment relations, paleoecological reconstructions, and the initial period of human settlement of southern Central America. Since then, the volume of archaeological work has steadily increased, helped by the presence of several local institutes and a combination of both US or European field research by dedicated archaeologists and their students as well as multiple edited volumes published between the 1980s and now.

Human Adaptation and Mobility

A returning theme of interest for research is the role of human mobility in the prehistory of southern Central America. Depending on the period under discussion, tropes such as colonization, dispersal, and migration are introduced in the different national archaeologies. Such archaeological discussions receive additional input from genetics, linguistics, and observations found in early Colonial period historical documents. While several decisive occurrences mark the long period from 11,500 BP onward, the events around AD 300–600 (cf. Hoopes 2005) impacted the cultural landscape of the southern Central America, and the social dynamics that have underlain such changes have received the bulk of archaeological study. The most important sources of information that support such migrations are linguistic and ethnohistoric in nature, with supporting indications coming from changes in the decorative style of polychrome pottery. Archaeological research focused on ethnic identification, and the direct sourcing of materials involved in such human mobility has, however, produced mixed results, highlighting the complex relation between historical writings (based on

indigenous oral history) and the traces of human action as recovered archaeologically.

A second focus on human mobility argues for back migrations (after initial dispersal) from northwest South America into Panama, Costa Rica, and further along the Caribbean side of Central America, including the Honduran Mosquitia region. This argument gives rise to the mentioned Isthmo-Colombian or Chibchan archaeological area thesis (Fonseca 1994; Hoopes and Fonseca 2003), and its formulation resides principally on contact deduced from shared material culture, motifs, and technology and later also combined with common linguistic roots and mitochondrial DNA studies. This thesis rests in part on certain iconographic foci depicted on objects fashioned out of gold, ceramics, ground stone, and lustrous jade-like polished stone and including a regional preference to depict double spirals, crocodilian motifs, and humans in a state of transformation. The ample archaeological relations to parts of South America help to illustrate the definitional complexity of an archaeology of southern Central America.

Paleoindian Period

The record for the earliest evidence of human activity in southern Central America does not allow for a regional reconstruction of sufficient detail, keeping in mind that securely dated South American Pleistocene sites such as Monte Verde have yielded dates of 14,500 BP with even earlier dates still possible (Dillehay et al. 2015). In general, the peopling of the Americas remains a highly debated research focus, with different views on initial points in time, routes, and chronological development. For southern Central America, the most substantial data set able to contribute to this debate come from Panama, where the earliest traces of human-induced vegetation changes and documented artifacts date to approximately 11,500 BP (Cooke et al. 2013). These would have been small and highly mobile hunter-gatherer groups, occupying rock-shelters for habitation and roaming between coastal and more highland regions, hunting for large fauna. Water locked in land ice resulted in lowered sea levels by as much as 100 meters relative to current levels before the end of the Late Glacial Maximum (13,000 BP). Significant areas of land were left exposed, greatly changing the coastlines of southern Central America. One example of this would be the entire Bay of Panama, which was a plain covered with deciduous vegetation. Climatological conditions were also different from later Holocene averages (which stabilized to current values around 8000 BP), with mean temperature dropping several degrees centigrade, and precipitation levels also lower compared to today. Toward 10,000 BP, the dwindling numbers of large game, combined with the warming trend, probably gave rise to a focus on biota consisting of smaller animals and a greater diversity of edible plants in the diet.

Preceramic Period

At the onset of the Holocene around 10,500 to 10,000 BP, the technologies used for fashioning lithic tools are still firmly based on flaking in order to produce for example unfluted and fluted projectiles, but this period now also sees the emergence of ground stone tools, indicative of the increased processing of plants. Outside of Panama, convincing data from other southern Central American regions remains very spotty, although it can be assumed with some confidence that small groups accessed all geographical regions of Central America right from the outset of the Holocene, including the Caribbean lowlands and highland mountain ranges. Thick volcanic deposits along the Pacific coast, obscuring preceramic sites, likely play a role in this as well. In the case of central Panama, groups appear to become more selective in choosing locations for habitation, and there is evidence for clearing of forests by burning. Further insights gained primarily from coring lakebeds point to the first indications of root crop domestication between 9000 and 8000 BP (Piperno et al. 1991). The intensity of human activity further increases in central Panama toward 7000 BP, with more extensive evidence for forest clearings, accompanied by the occasional traces of habitation in rock-shelters. Also, maize appears for the first time in the paleoecological microfossil record around 7600 BP, and it is likely that the adoption of maize cultivation is causally related to the observed further decrease in

primary forest. Domesticated in the southwest Mexican state of Guerrero around 10,000 BP, maize dispersed rapidly through southern Central America and into South America, but how it did so remains another widely debated and researched topic. Reliable data for following this dispersal trajectory is found in central Panama and Costa Rica, with little excavation data coming from elsewhere in southern Central America. Similar to later data from parts of Caribbean regions, palm nuts and other types of fruit-bearing trees also form part of the diet during this period.

First Pottery

There is convincing evidence for early pottery outside of southern Central America, from the San Jacinto site in the foothills of northwest Colombia (5900–5300 cal BP), but the earliest forms of pottery in Central America are presumed to be independent inventions (Hoopes 1994). Such pottery may have initially served for storage purposes alongside natural gourd containers or possibly also for competitive feasting (Hoopes 1995). Alongside pottery, the first traces of refuse piles, including shell mounds, are known from Pacific coastal bay areas in central Panama, and traces of early domestic structures are documented at the Tronadora Vieja site around the Arenal Volcano in Costa Rica around 3800 BP.

Around 5500 cal BP, the first traces for pottery manufacture appear in the archaeological record of southern Central America. This data comes from coastal and inland sites in Panama, including Monagrillo (5470–3250 cal BP). Somewhat later are ceramic deposits from northwest Costa Rica (4000–2500 cal BP). This Tronadora-style pottery from northwest Costa Rica, though rare in occurrence, may be indicative of materials found along the wider Pacific coast further north toward Nicaragua and south toward western Panama and into the Caribbean lowlands. The developed technology of this pottery, however, suggests even earlier, as yet unidentified, forms (Corrales 2000).

Though based on a fragmentary data set, the last two millennia BC show a pattern of rising human impact on the environment with coring data showing further decreasing primary forest taxa and an increased reliance on domesticates such as maize, manioc, squash, and sweet potato. Simple fishing in tidal pools is beginning to expand to more advanced shoreline fishing technology, documented in the Parita area at the Bay of Panama, involving nets and possibly using simple canoes or other forms of flotation. For southern Central America in general, it can be assumed that the adoption of a more agricultural lifestyle, including the production of pottery, took place over a long timeframe, with groups living in tropical montane regions continuing a foraging subsistence strategy while those in seasonally drier environments relying more on cultivated staple crops. From around 500 BC onward, the archaeological record becomes far more varied across southern Central America, with production and exchange in material culture increasing and the first patterns in settlement location becoming apparent. It is also this period (500 BC–AD 1520), upon which the majority of past and current archaeological investigations are focused. Such investigations invariably are contained to one country, as reflected in the country discussions below.

Honduras

With Maya societies living in the extreme western regions of Honduras, the main central, northern, and eastern parts of the country reveal a complex zone of communities interacting to various levels from approximately 1000 BC onward. Most of these early sites are situated in various Honduran intermontane valleys, such as Ulúa, Lake Yojóa, Naco, and Comayagua. Already at this relatively early stage, communities were taking part in interregional interaction networks reaching into Mesoamerica, as evidenced by pottery made locally but stylistically reminiscent of Olmec objects. This is perhaps unsurprising given the macroregional importance of the regionally unique source of jadeite in the Motagua Valley of Guatemala and the role of cacao as a product from the tropical regions of Honduras, sought after in societies far beyond local cultural horizons (Healy 1984). During this first half of the last millennium BC, we also see the first evidence for mound and raised platform construction (Joyce 2004).

Following these early expressions of monumentality is the advent of the hallmark Usulután

ceramic style, spreading through much of Honduras and El Salvador from the latter half of the last millennium BC and in use up to roughly AD 400. Due to its distinctive orange and cream appearance, combined with resist decoration, and a specific range of rather fine pastes, Usulután ceramics are the most highly diagnostic ceramic ware in Honduras during this period. While for a long time considered a trade ware, more recent neutron activation and petrographic studies are changing this view, pointing instead to various local production points. Usulután wares are documented in most of the sites excavated in the mentioned Honduran valleys, with the exception of the northeastern region where it is noticeably absent. The advent of Usulután is accompanied by increases in site density and overall contacts between and beyond these regions.

During the centuries after this, up to about AD 1000, mound and platform construction continues to intensify, introducing ball courts (typical for Mesoamerica) into both central and eastern Honduras, expanding ceremonial mound-lined plazas and showing signs of possible site ranking in two or three levels. New earthworks are added to those at previously occupied sites, not infrequently obscuring earlier constructions. Apart from this steady intensification of building activity, this period is signaled archaeologically by the appearance of the so-called Ulúa-Yojoa polychrome wares and interaction with the major Maya settlement of Copán. The Ulúa-Yojoa polychromes, a broad category of decorated pottery, including flat-bottomed cylindrical vessels, has a long history in the archaeology of Honduras and is documented stylistically in excavations in Nicaragua, El Salvador, and even Guatemala (Joyce 2017). Alongside this polychrome group, the second defining object class is a small but distinctive corpus of cylindrical vessels sculpted in marble, produced in limited numbers at a specific workshop at the center of Travesía in the Ulúa Valley, and appearing in sites in the Maya lowlands and Pacific Nicaragua. Both the increase in monumental architecture and the evidence for craft specialization may help in arguing the stability of the communities responsible for this activity. While authors have argued for the emergence of incipient chiefdoms in his period, there is little evidence, for example, from funerary settings, for any form of chiefly elite, leaving open the alternative explanation by means of heterarchical cooperative structures.

The period from AD 1000 onward shows a decrease in building activity in many of the Honduran valleys. A straightforward link to the population decline is observed at Copán a century or two prior to this period, invoked by the so-called Maya Collapse. Although the intensity and velocity of this decline is the topic of ongoing debate, it is likely that any mayor change would have entailed consequences for other Honduran regions. Although there is a decrease in the previously seen rise in sites and possibly also in population density, it is not a period of sharp shifts in settlement patterns. Numerous sites continue to be occupied after AD 900, including Las Vegas and Los Naranjos, and Copán itself continues to show some activity. The Naco Valley is one of the best studied areas for this period. Sites there are known to have played a central role in coastal trade networks reaching from the coasts of Honduras, across the Yucatán peninsula, to the Gulf of Mexico. Recent research in the Naco Valley sites highlight the negotiation of authority and local political hierarchies, using networks of exchange to bring in exotic materials (Schortman and Urban 2011). Interaction networks to other parts of southern Central America are also evidenced by moderate amounts of Greater Nicoya white-slipped polychrome decorated pottery at sites in central Honduras as well as elements of styles from Honduras, Nicaragua, and Costa Rica. Contacts toward Mesoamerican subregions are indicated by the presence of small amounts of copper objects and a few instances of the trade ware ceramic-type Tohil Plumbate from El Salvador at Copán and on the Bay Islands off the Caribbean coast.

In the northeastern region, site surveying and mapping has produced evidence for substantial habitation after AD 1000. Numerous sites, some of which in defensible locations, show considerable elongated mound-plaza architecture, exceeding sites from previous periods in size and planning. Overall, these sites still do not adhere

to a self-evident orthogonal layout, instead combining architectural elements depending on local topography, drainage, and vantage points, but the increase in overall planning is evident. In terms of material culture, there is a noteworthy orientation toward the Caribbean lowlands of Nicaragua and Costa Rica, with a tradition emerging of sculpting stone monoliths and fashioning elaborate milling stones. Most recently, an investigation into coastal sites was initiated to better understand existing local typologies and regional relations. Despite this work, and its being one of the largest regions in Honduras, the northeast remains one of the archaeologically least-known parts of southern Central America.

The archaeology of Honduras reveals connections of stylistic forms and materials to Central American regions further south. Furthermore, there is a relation of selective exchange through the network node of Copán and beyond this to trade routes from more central parts of Mesoamerica. From the last millennium BC onward, and continuing into the last centuries before the Spanish Conquest, such networks, while subject to periodic change, remained a constant feature, evidenced primarily through the trade in rare commodities. Simultaneously, site layouts and structures, and more regional level settlement patterns, seem to have maintained a certain level of resilience in their trajectories within the multiple valleys that mark the cultural landscape of Honduras. While major macroregional changes like the Maya Collapse during the ninth century AD were certainly not without their effect, complete ruptures of past cultural patterns and connections seem to not have occurred. In fact, northeast Honduras saw an increase in activity and the proliferation of material practices, possibly intensifying ties with Caribbean regions further south.

The Gulf of Fonseca and Eastern El Salvador

The Gulf of Fonseca is shared by eastern El Salvador, southern Honduras, and northwest Nicaragua. This is one of the most particular coastal features of southern Central America, marked by extensive mangrove forests and tidal flats, alongside delta-like mud plains. A number of islands dot the Gulf, and numerous rivers discharge their water coming from the valleys of central Honduras. The Gulf is a product of active tectonics, leading to faulting and volcanism occurring along the wider Pacific coastline. There is considerable uncertainty about the archaeology of this region, even though it is likely to have featured substantially as an area of fishing in prehistoric times. In macroregional perspectives, the Gulf is typically seen as a waypoint in the networks of exchange that are argued to have existed along the Pacific coast. For AD 800 and later, it forms an as yet unresolved nexus between more southern Central American-oriented communities and those more strongly resembling Mesoamerican cultural patterns. Notwithstanding this regional uncertainty, substantial archaeological work done on the Gulf region is lacking, with past research documenting several small settlements and salt-making sites on the Honduras side of the coast with human activity going back to AD 300 and continuing until the arrival of the Spanish (Baudez 1976). Despite this dearth of research, there are indications that the Gulf filled an important role in interzonal economic exchange between local coastal communities and those further toward the interior in the surrounding valleys. Such "vertical" interaction merits more scholarly attention, as southern Central America overall is a region with an above-average amount of coastal zones relative to inland surfaces.

Starting west of the gulf and naturally bounded by the Lempa River, eastern El Salvador demonstrates connections to the material culture of southern Central America by means of contemporaneous presence of certain ceramic types or trade wares during the last millennium BC and the first millennium AD. Especially widely recorded Usulután-style pottery appears in significant quantity at eastern El Salvadoran sites such as Chalchuapa and Usulután (the site after which the ware is named). Between AD 1000 and 1200, the presence of Papagayo Polychrome pottery, having its origin in Pacific Nicaragua (see below), is indicative of connections of eastern El Salvador with more southern regions. In the regional perspective, the archaeology of eastern El Salvador is a crucial connection in evaluating the changes in relations between southern Central

America and more northern regions, such as the Maya lowlands, the Gulf Coast of Mexico, and southern parts of Mexico. The more prolonged studied site Quelepa provides strong evidence for such diachronic shifts in macroregional connections (Andrews 1976), which, perhaps remarkably, appear to exclude the Maya center of Copán.

Pacific Nicaragua and Northwest Costa Rica

Around 1000 BC, the earliest traces of habitation are documented in parts of Pacific Nicaragua and northwest Costa Rica in the form of shell middens and hearths associated with diagnostic incised and striated monochrome and bichrome ceramic wares. Funerary practices are varied in form, including both secondary urn burials and primary extended interments, the latter often with three- or four-legged grinding stones or stools present, on which the deceased is sometimes placed. Further grave goods can include polished stones made of jadeite or visually similar materials and ground stone mace heads. While archaeological data remains scarce for this period, it is accepted that it continues to up to around AD 500, when polychrome pottery types appear and there is a subsistence shift to include exploitation of maritime resources. From AD 800 onward, the material culture in Pacific Nicaragua shows strong resemblances to that found in northwest Costa Rica (principally the Nicoya Peninsula), and this similarity in pottery is the background for the notion of the Greater Nicoya archaeological region. As with most other regions of southern Central America, its boundaries are only approximately defined, but it is generally understood to envelop the shores of both Lake Xolotlán and Lake Cocibolca and the foothills of central Nicaragua, as well as reaching up to the Gulf of Fonseca. For northwest Costa Rica, the Nicoya peninsula and the Tempisque River Valley are the primary features, with the Tilarán mountain range forming a natural southeastern extremity.

In contrast to the other regions discussed here, Greater Nicoya was originally defined to denote an extension of the Mesoamerican culture area (Lange 1984). This initial proposal was motivated by ethnohistoric similarity to Mesoamerica (Kirchhoff 1943), later evidenced by a combination of regionally shared changes in pottery, including motifs and symbols appearing on polychrome ceramics in the region, alongside developments in lithic technology, and ethnohistoric references to migration of Mesoamerican language speakers into the region sometime around AD 800 (Norweb 1964). By now, Greater Nicoya is recognized as a region with strong local cultural dynamics, even when exhibiting a relatively high amount of identical ceramic types when compared with surrounding archaeological regions of Central America (Healy 1980). Compared to other regions of southern Central America, several parts of Pacific Nicaragua and northwest Costa Rica are at least to some degree known archaeologically, with several projects taking place since the 1960s. Prior to AD 900, there is considerable uncertainty about the archaeology in this region, and it may well have shared cultural patterns with the Caribbean regions of Nicaragua and Costa Rica. Similar to patterns in central Honduras, the first examples of exchange with Mesoamerica date back to at least 500 BC, with early pottery forms showing resemblances to other types found along the Pacific coast toward Guatemala and southern Mexico. Intensity and continuity of these connections, however, remain poorly understood. From 500 BC onward, Usulután-style ceramics also appears in parts of Greater Nicoya, possibly made in local workshops.

In addition to the proposed cultural affiliation to Mesoamerica, the notion of Greater Nicoya also rests on geographical features, perhaps more so than other southern Central American archaeological regions. Chance events, such as volcanic eruptions, had immediate and long-term effects on the development of pre-Hispanic communities in Greater Nicoya. The coastal regions of Nicaragua are defined by the two freshwater lakes and a strip of land separating Lake Nicaragua from the Pacific Ocean by as little as 19 km at one point. This corridor-like geography was likely a preferred route for down-the-line exchange networks throughout the pre-Hispanic sequence, and excavated settlements in Pacific Nicaragua dating to AD 300 show the movement of materials such as obsidian from other parts of southern Central

America, including the central valleys of Honduras and parts of eastern El Salvador.

Possibly tied with migratory movements from Mesoamerica, a series of changes in regional settlement patterns, funerary practices, and material technologies occurs around AD 600 (Hoopes 2005). From this moment on, up to the arrival of the Spanish, pottery finishing shows innovations and changes that have enticed scholars to argue a scenario in which Greater Nicoya took part in a macroregional exchange network, involving the transfer of materials and symbolism. The latter is principally argued through the growing presence of polychrome ceramics in combination with the appearance of new motifs and innovations in finishing techniques, including distinctive white-slipped ceramics in Pacific Nicaragua and orange-slipped types in northwest Costa Rica. Attesting such migrations, as a direct cause of the changes in material culture, however, has proven elusive (McCafferty 2015). Instead, based on earlier foundational studies, the increased comparative stylistic study and technological sourcing of such pottery is placing greater emphasis on more localized production processes. The current understanding is that pottery production is largely a local process, within and between the northern and southern parts of Greater Nicoya, and appears less significantly linked to exchange beyond Greater Nicoya itself.

Apart from the archaeologically challenging topic of Pacific coastal migration from Mesoamerica into Greater Nicoya, the period from AD 600 and the increased connections of Greater Nicoya to southern Central America developed into that of a node in the long-distance trade of social valuables produced in parts of Panama and Costa Rica. Although not overwhelming in number, hammered gold disks do show up in various late contexts in the Maya region and the central highlands of Mexico. Metal objects are far from ubiquitous in archaeological contexts of Greater Nicoya, and it is an unresolved question how the itinerant presence of such novel shiny objects would have impacted on societies in Greater Nicoya. Any increase in connections between both regions opens up the question of what the probably quite different human relations to exotic materials could have been, keeping in mind that stylistic comparability need not indicate shared ideas and the new materials and styles would have been perceived as new possibilities and extending ideas on the nature of the wider southern Central American world. Notwithstanding such a wider role for Greater Nicoya, it is one of the archaeological regions in southern Central America where continuity and stability of both population density and organization, as well as practices of pottery production, are most remarkable.

Beyond the immediate Pacific coastal areas of Greater Nicoya, the variable topography, soils, and microclimates make for a more challenging comparison to other parts of this region traditionally considered to skirt Greater Nicoya. The numerous islands in the two lakes principally include Ometepe, Zapatera, and the Solentiname archipelago, with considerable indications of human use, but overall there are several hundred smaller ones, all of which feature at least some form of archaeological traces of prehistoric habitational, funerary, or ceremonial activity. Across from Lake Cocibolca, the expansive and loosely defined region of central Nicaragua represents the transitional zone toward the Caribbean lowlands and with intense building of mound-like surface structures, both adapted to local topographies as well as built to form the large ceremonial complex of Aguas Buenas (Geurds and Terpstra 2017). This region, and others connecting Greater Nicoya to central mountainous and Caribbean geographies, harbors the potential to provide further detail to how indigenous communities were enmeshed in relations around natural features such as the mentioned lakes.

Caribbean Nicaragua and Costa Rica

The Caribbean coastline of Nicaragua and Costa Rica is a region of dense tropical forest cut by numerous rivers. In recent decades, significant deforestation resulted in barely connected pockets of forest in the midst of grasslands used as cattle pasture. Partly as a consequence of the impenetrable character of the region, combined with the high degree of precipitation, the archaeological narrative here is still largely relying on individual

site excavations or valley-based surveying, and a detailed understanding of diachronic developments is unavailable. What can be reported is more often than not based on single finds, often the product of salvage interventions, than being the product of long-term archaeological research projects.

Research on the central Caribbean coast of Nicaragua points to the exploitation of marine resources, as evidenced by substantial shell middens documented near the modern town of Bluefields. These sites, lacking in surface domestic architecture, are identified as temporary camps used for fishing, harvesting gastropods, and catching turtles, all possibly for eventual transport and distribution upriver by canoe. Farther inland, the scant archaeological data points to communities relying primarily on agriculture. This appears to have been based on maize, given the abundant presence of grinding stones. This model may in fact not diverge much from the abovementioned subsistence strategies deployed at the Gulf of Fonseca and provide one more example of the attention needed for human adaptations to coastal-inland subsistence strategies.

A second study in Caribbean Nicaragua has documented an example of public ceremonial architecture and the use of stone sculpture (Geurds in press). At the El Gavilán site, just east of the modern town of El Ayote, a site featuring numerous low clay mounds as well as a few considerably higher ones is complemented by two square platforms. These platforms are directly associated to a large cluster of carved and uncarved monolithic sculptures, up to 2 meters tall. This high degree of sculpting activity echoes finds from parts of Caribbean Costa Rica in also being focused on representing human bodies, although it is technologically distinct. The site is situated directly at the confluence of two rivers, placing El Gavilán at an advantageous location for regional gatherings. The monumental layout of the site possibly created a spatial context for conducting public activities involving communities from both up- and downriver. Moreover, the required practices of selection, extraction, transportation, and carving of these monoliths indicate a highly skilled and organized activity. While hypothetical, such a role for establishing and confirming social ties would have been beneficial to the communities in the wider surroundings. A monumental location such as El Gavilán provides rare insight into the conditions needed for the reproduction of shared histories among those participating in its construction, as regional community ties were cemented and maintained in the process. Similar to the studies arguing for river transport for subsistence practices, the location of this ceremonial site also underscores the importance of rivers as expedient ways of transport, highlighting the rivers role as facilitator of contact in southern Central America.

For parts of the lowlands of Caribbean Costa Rica, south of the San Juan River, the data resolution is better. At the relatively early date of approximately 100 BC, settlements begin to emerge, typically situated in valleys with alluvial deposits, practicing both seed and root crop agriculture. What is remarkable about the material culture of the excavated sites from this period is not so much the domestic or public architecture but the extensive funerary customs, specialized working with lapidary materials (including serpentinite, chalcedony, and other silicate rocks optically similar to jadeite), and a developing practice of fashioning ground stone objects. Overall, the early rise in cultural activity in Caribbean Costa Rica may be related to wider macroregional interaction networks, evidenced again by Olmec style objects (Snarskis 1984). Determining the routes along which such networks may have been established and maintained is a function of defining features in the geography of southern Central America. As such, connections from southern Honduras and perhaps the Gulf of Fonseca, along possibly either side of Lake Nicaragua, into northwest Costa Rica, would have been favored, and from there on forking along the central mountains toward the Caribbean and the Pacific coastal area of Costa Rica.

From AD 400, further noticeable changes occur in Caribbean Costa Rica, with earlier sites showing continued occupation and additional settlements being established in this second half of the first millennium AD. Gold objects become more visible in the archaeological record, and jade-like

materials decrease markedly – a process seen more widely in southern Central America in this period. Circular house areas become the norm over the previously seen rectangular footprint, and the use of wide cobblestone paths and pavements is common. Sites such as Guayabo de Turrialba and Nuevo Corinto are prime examples of such forms of housing and also provide indications for chiefly or communal residences. Funerary practices revolve around stone cist structures in a variety of shapes and include the use of flagstones for retaining walls, top cover, and even laying out the tomb floors. A specialized practice of highly decorated and distinctive ceremonial grinding stones is also found from this moment on, as well as various forms of human sculpture, either seated or standing and displaying themes related to warrior identity and trophy heads (Hoopes 2007). Again, it has been argued that these changes in Caribbean Costa Rica are caused by long-distance contacts, more specifically a change from Mesoamerican trade routes, to strengthening southern connections into the Greater Chiriquí and other parts of Panama and into northwestern Colombia.

Southern Costa Rica and Western Panama

Parts of southern Costa Rica and western Panama, respectively, known as the Diquís Delta and the province of Chiriquí are collectively referred to as the Greater Chiriquí archaeological region. This concept was originally proposed exclusively for the Pacific coastal slopes of both countries (Haberland 1976) but was expanded to include the Caribbean side of this part of southern Central America as well (Haberland 1984), with the Cordillera de Talamanca as a central geographical separation. While useful as a general frame of reference, the Greater Chiriquí regional definition remains ambiguous on several sides. Uncertainty continues to exist about its northeast boundary, toward the central coastal parts of Costa Rica, as well as regarding the western boundary toward the central Panamanian Greater Coclé region. Additionally, the exact cultural relation of the Caribbean region in the Greater Chiriquí remains under debate. The fragmented geography in this region, consisting of a diverse set of river basins, bay areas, coastal plains, and highlands, may eventually lead to the definition of further cultural subdivisions. While some patterns in ceramic styles and site characteristics referred to as the Aguas Buenas Period are discernible from AD 300 onward, how far back in time this extends is again subject to discussion, with dates as early as 1500 BC also being considered (Corrales 2000), and archaeological patterns varying considerably throughout the region. Integration of communities at the regional level was seemingly limited until AD 800, despite similar ceramic types being spread across the region. In response to this uncertainly, archaeological research has proposed several more localized sequences for the period before AD 800, perhaps indicative of the substantial cultural diversity in the Greater Chiriquí before this date (Corrales 2000).

Cultural developments from AD 300 up to the arrival of the Spaniards are marked by one generally recognized period break around AD 600. From this moment onward, settlements become more complex in their composition and are associated with alluvial plains, and their locations are increasingly co-dependent on access to marine resources (Drolet 1988). In fact, given the varied topography and vegetation, it is assumed that settlements will have had access to multiple food sources, alongside what was being cultivated. Similar to other regions of southern Central America, communities were often composed of both ordinary domestic residences as well as public spaces such as communal plazas and stone monuments, including a unique tradition of fashioning large spheres out of gabbro or limestone, declared UNESCO World Heritage in 2014. Graves were placed on hilltop settings, or in mounds near domestic spaces, with grave goods prominently including distinctive peg-based stone sculptures. Rounded river stones were used for the construction of raised platforms, and served in laying out planned pavements and causeways, comparable to those described for Caribbean Costa Rica. The constructing of mounds was not as ubiquitous as it was in parts of central Nicaragua, with mounds being restricted to certain locations in settlement. Given their increased dimensions and elaboration, they are presumed to have served a more exclusive purpose for the community's leadership and their families. There

is ample evidence of maize processing previous to AD 600, but this further intensified after this date (Horn 2006), possibly causally linked to the mentioned marked shifts visible in material culture and community organization. Although gold metallurgy first appears as early as AD 200, an additional defining feature of the period after AD 600 is the expansion of metallurgical production, with especially gold being mined and worked in different parts of the Greater Chiriquí. As different as they will have seen the southern Central American world once they had arrived there, accounts by the Spanish also provide fairly detailed reports on the territorial organization of parts of the Greater Chiriquí region, highlighted by the presence of chiefs and multiple political boundaries in the region, as well as references to the frequency of intercommunity conflict about territory, goods, and captives (Corrales and Badilla 2018).

In the Panamanian province of Chiriquí, there are strong indications of communities gradually developing a certain level of institutional leadership. This is evidenced through specialization in tool production activities in multiple villages, the manufacture of monumental stone objects, including human sculpture. The site of Barriles is one of the more cited examples of the rise in arguing sociopolitical complexity in the Chiriquí. Barriles in fact consists of two related sites and is located in the proximity of the Barú volcano which has a wider set of settlement on its outskirts (Linares and Ranere 1980). Early research at the site yielded a massive four-legged ceremonial grinding stone, several meters in length, and lined with sculpted human heads. Another unique object category is the stone barrel-shaped objects, after which the site is named. Although the cultural sequence at Barriles goes back to at least AD 300, the further development of Barriles, and possible other sites of this magnitude, is linked to population growth made possible by an increasing reliance on maize agriculture after AD 600. Whether the advent of intensive maize cultivation is directly causally related to population growth and the emergence of chiefly territorial leadership or if the two developments proceeded in a rather parallel dynamic is debated (Hoopes 2005). Similar to other studied archaeological sites in coastal Pacific Central America, the occupation of Barriles was influenced by a substantial volcanic eruption. This eruption left a clear mark on the stratigraphy, but its dating to around AD 600 is now considered problematic. Accordingly, an active local exchange network was maintained featuring pottery, stone, salt, and staple foods. Overall, from AD 600 onward, the Greater Chiriquí thrived as a region with a diverse settlement pattern, connected to regional trade routes linking Greater Nicoya and central Panama.

Central Panama

East of the Greater Chiriquí region, central Panama has revealed the temporally deepest archaeological sequence of southern Central America. As discussed above, the first data on human activity in central Panama dates back to the Terminal Pleistocene and become more detailed leading up to approximately 500 BC, with patterns of human adaptation to the environment enveloping both the Pacific and Caribbean sides of the region. A rich data set attesting the development from hunting and gathering to include fishing and the adoption of agriculture is evidenced. Between 500 BC and AD 0, settlement locations and agricultural activities shift from foothill areas down to lower alluvial river valleys nearer to the coast. Approximately from this moment onward is when prehistoric activities in this region are referred to as the Greater Coclé tradition (Cooke et al. 2000).

Two parallel developments beginning around AD 200 define the emergence of the Greater Coclé tradition: the development of a number of highly distinctive trichrome and polychrome pottery styles, accompanied by the arrival of metalworking practices having their direct origin in Colombia. The tri- and especially polychromes ceramic types form one of the most ornate and richly decorated pottery styles in southern Central America, perhaps together with the Greater Nicoya polychromes. Coclé-style motifs include supernatural creatures, a range of geometric and organically shaped designs, and various animal depictions as part of other forms of decoration. The practice of trichrome painting on pottery begins around 200 BC and that of polychromes around AD

700 and runs diachronically, through individual styles all the way to the arrival of the Spanish, each style spanning several centuries. Metalwork motifs overlap to some degree with these polychrome styles. How this tradition was organized territorially is the subject of some discussion, with the Pacific coast of Central Panama serving as an oft-cited comparative case study of social hierarchy and chiefly leadership in the Americas. The emergence of such chiefly polities was possibly related to the increasing reliance on maize in the diet of communities in Central Panama. Even though wild fruits and palm nuts are still used, the prominence of maize is shown archaeologically both in starch analyses on grinding stones as well as through stable isotope signals in human bone.

Spanish references frequently mention chiefs and the territory they occupy in Central Panama. These descriptions provide tantalizingly precise observations, many times difficult to verify archaeologically. It is fair to assume that communities featured at least some level of sociopolitical stratification and they were organized based largely on kinship relations. Not every community or settlement will have participated in this political landscape in the same way. In this Pacific coastal environment, the site of Sitio Conte has stood out given the lavish graves dated to AD 700–900. More recently, the site of El Caño, previously only known for its alignment of carved monoliths, has revealed burials of similar complexity and elaboration (Mayo and Mayo 2013). The sumptuary goods found in these funerary settings are some of the most diverse and impressive known for southern Central America, in spectacular nature rivaling those found in parts of Mesoamerica and the Middle Andes. The leadership authority implicated in such grave finds appears to accord with traditional definitions of chiefly ranked societies, but if this site – identified by its excavators as a necropolis – was in fact an interterritorial burial ground or situated in a single political territory remains unresolved.

The archaeology of Central Panama contributed to comparative analyses on the origins of chiefly leadership, also beyond southern Central America. One argument has recognized the link to individual performance in episodes of conflict between societies and the ability to control and interpret exotic goods, exchanged or personally procured beyond societal horizons. This developed notion on the social and political value of esoteric knowledge forms a widely cited study on elite strategies of wealth and authority (Helms 1979), stressing the importance for chiefly legitimation of having access to the acquisition and interpretation of exotic valuables. A substantial body of research into the development of subsistence strategies in central Panama, however, argues for a more local sociopolitical dynamic whereby technological changes in food procurement and preparation, as well as increasing use of gold ores, are the source of differential access to and control over these resources, leading to wealth and display of authority.

Eastern Panama

Eastern Panama is simultaneously one of the archaeologically least known and most relevant regions to discuss. It is culturally part of what is referred to as the Greater Darien (Cooke 1984), including the northwestern Colombian region around the Gulf of Urabá, the Atrato River, and parts of the Chocó department running along the Pacific coast of Colombia. As mentioned, it has some of the earliest documented pottery traditions in the Americas and also was the avenue through which metalworking made its way north into Central America. Metallurgical knowledge was probably in place in parts of Colombia around at least 500 BC, with examples from central Panama following around AD 500, and then developing into a wide variety of styles, and further technological specializations to fashion ornate gold or *tumbaga* (copper-gold alloy) objects, including pendants, breastplates, and ear and lip plugs. The modern national boundary now obscures what was the environmental continuity of eastern Panamanian rain forests and those on the other side of the Colombian boundaries in the Chocó region and also along the Caribbean coast of the Gulf of Urabá. As Bray argues (1984), eastern Panama likely constituted a single cultural region from around AD 0 onward, defined by the use of tumbaga

pendants featuring a complex iconography and an equally specialized metalworking knowledge. Archaeological data in Greater Darien rely on the excavation of a very limited number of sites, prominently including Momil near the Caribbean coast of northwest Colombia. How the communities were organized in eastern Panama is empirically not well established, but the pattern of chiefdom level societies, as described in Spanish sources, is assumed to come into existence around AD 500. The indigenous societies of Greater Darien were to witness the first Spanish settlement in the mainland Americas in AD 1510.

Summary

Similar to other regions of the world, the prehistory of southern Central America is defined by cycles of transformation as well as a marked stability in how its societies defined themselves and related to others. Regional containers such as southern Central America and all the subareas described above are archaeologically useful heuristic devices, but not very informative on social realities and how human action shaped that what is now called the prehistory of southern Central America. Archaeological evidence indicates that communities roamed, changed, and settled the diverse landscapes of this American isthmus and in the process created a long-term dynamic of adaptation and mobility. Such patterned action is, in turn, recognized archaeologically, albeit with different resolutions across Central America. What marks this area region from a global archaeology standpoint are two main points: the extraordinary position in the midst of two continental landmasses and because of this, the unique role played by southern Central America in the initial human colonization of the Americas, perhaps globally late but with great velocity, and second, the remarkable stability of social life (as seen also in genetic and linguistic data) in the midst of forming part of macroregional exchange networks that saw jadeite, gold, and copper objects, among various other forms, spread through and across the region.

Steadily, archaeology is beginning to reveal that different forms of cultural expression from the earliest periods of human presence down to the advent of European colonization revolved around the indigenous communities' concerns of how to successfully negotiate regional cultural, linguistic, and social differences as well as the geographical character of the area. Such concerns were in part surely unconscious but in part also active decisions, as shown, for example, in the spread of certain pottery styles. All this resulted in communities, with a range of densities and forms of organization that existed contemporaneously and with extraordinary stability, until the sixteenth century.

After Christopher Columbus explored the Caribbean coasts of southern Central America during his fourth voyage in 1502, the period of Spanish incursions into Central America is a history of frequent violence and massive death. These events effectively ended the prehistoric period, even though for the vast majority of elements that defined indigenous life in southern Central America no historical writings would ever become available. Notwithstanding the cataclysmic changes occurring in the sixteenth century, indigenous settlement continued in certain areas until well after colonial administration of the region had begun. Evidence from sites such as Paso Real in the foothills of the Diquís region of Costa Rica, for example, shows European glazed ceramic wares and glass beads to be present in indigenous graves. However fragile, such continuity seems to mostly appear, perhaps predictably, in areas of very low population density and poor infrastructure.

Preservation Paradigm in Heritage Management

Cornelius Holtorf
School of Cultural Sciences, Linnaeus University, Kalmar, Sweden

Introduction

The idea of preservation is the basic paradigm of all heritage management, including archaeological heritage management. Heritage experts often take for granted that remains of the past are inherently valuable and deserve to be maintained in perpetuity. A common slogan thus proclaims the need to "preserve the past for the future" (cf. Spennemann 2007). Therefore, archaeologists and other heritage experts do their best to preserve sites, objects, and the information they contain for the future. Archaeological preservation involves either the conservation of heritage in physical

terms ("preservation in situ," "stewardship") or, in case a given site or object cannot be preserved physically, it involves recording and archiving the information it contains ("preservation by record"; "rescue archaeology").

The contemporary conservation ethos in cultural heritage is firmly situated in a specific historical and cultural context of European civilization of the past few centuries. The French architectural historian Françoise Choay (2001 [1992]: 139–142) used the phrase "Noah complex" and referred to "the religion of heritage," "the cult of the historical monument," and widely practiced "rites of an official cult of historic heritage." This was echoed by economic historian Svante Beckman (1998: 32–39) who observed a peculiar "sacredness of cultural heritage" (my translation) in society, evoking piety and reverence, and by historical geographer David Lowenthal (1996: 1) who in his book on *The Heritage Crusade* described the cult of heritage as a popular faith in which the world has now started to rejoice: "heritage [has] become a self-conscious creed, whose shrines and icons daily multiply and whose praise suffuses public discourse."

References to a Noah complex and a semireligious cult of heritage point to that aspect of the contemporary concept of heritage that is most notorious and that, in a future perspective, is likely to become most noteworthy: the obsession with conservation, preservation, and protection. According to some commentators, conservation and preservation issues have taken over nearly the entire range of legitimate ways of being interested in the past. This is, for example, the main thrust of David Lowenthal's study (1996) in which he argues that the lure of a heritage to be conserved now outpaces all other modes of relating to the past including tradition, memory, myth, memoir, and history. And in the words of archaeologist Graham Fairclough (2009: 158), one might add that

> [t]he obsession with physical conservation became so embedded in twentieth century mentalities that it is no longer easy to separate an attempt to understand the past and its meaning from agonising about which bits of it to protect and keep. It is almost as if one is not allowed to be interested in the past without wanting to keep or restore . . . the remains of the past, which seem to exist only to be preserved. The wide range of how the past is used by society has been reduced to the literal act of preserving its fabric. In that sense, history has been subsumed into heritage, scarcely having any independent existence.

Current Debates

The logic of the preservation paradigm of heritage insists that what is valuable deserves to be protected and preserved by stewards for the benefit of future generations. Lately, this logic has however rightly attracted criticism (e.g., Hollowell 2009; Holtorf 2015).

Preservation is sometimes presented as practiced from a position that is located outside history and based on experts assessing changes over time rather than their judgments manifesting such changes. But from a life-history perspective of monuments and landscapes, heritage preservation can be considered as one major way of reinterpreting and reusing a given site or landscape in our age. This history of a site and the story heritage can tell are enriched by additional layers of meaning and their physical manifestations, e.g., related to contemporary heritage tourism. This includes even destructive processes such as erosion or vandalism, which raises a series of important questions. Given the way in which archaeological preservation and destruction are often entangled at the moment of discovery, when heritage is presented to various audiences and through the act of visiting and studying it, how can we separate one from the other? Are there conditions under which loss of heritage can be beneficial for future generations? How significant are stories about the past told by vandalized or obliterated heritage? Can the consumption and use of heritage for present benefits be more important than its preservation for the future? Does an obsession with preservation and stewardship of archaeological heritage prevent us from making informed decisions that are in the best interest of a majority of living people? Whom are the stewards

of heritage actually accountable to and on what grounds? Do we have to distinguish benefits for different groups of people? When will the future arrive in which the heritage can be consumed? If it never arrives, why preserve? Is not cultural heritage and its management inevitably subject to historical change over time and eventually bound to be overcome?

It is far from certain whether or not preservation is contributing to shaping a future we want to live in. In an interesting debate on BBC News (2009), triggered by a recent cash crisis at the site of Auschwitz, the question raised was "Should Auschwitz be left to decay?" Historian Robert Jan van Pelt argued that once the last survivor has died, the site as such will have little to tell to future visitors and should therefore be closed and peacefully left to decay out of respect to all those who died there. **Władysław** Bartoszewski, Chairman of the International Auschwitz Council, on the other hand, suggested that the site should continue to be preserved as a burning wound, to bear witness to the tragedy that happened there and as a future warning against all forms of contempt for mankind. Who is to say whether or not Auschwitz in 100 years from now will still be preserved and appreciated in ways we would approve of?

The present concern for future generations in the heritage sector (as elsewhere) is neither a matter of altruistic self-sacrifice for the welfare of future human beings nor one of intergenerational equity. As the past and its remains are continuously growing every day, future generations cannot run out of past, and there will always be plenty of cultural heritage to study and enjoy. Given the changing notions of authenticity and fast-developing techniques of copying and reconstructing, it is also dubious whether the values of archaeological heritage are really nonrenewable (Holtorf 2005: Chaps. 7 and 8). Indeed, it may be counterproductive to become too good at conserving heritage. Since future generations may perceive as less valuable what is common, they might become less appreciative and careful toward abundant heritage than they would otherwise have been – effectively rendering our own conservation efforts meaningless.

Archaeological heritage managers do not professionally engage with the question which future they are working for and how their work will impact on that future (Högberg et al. 2017). Arguably, the obsession with preserving heritage during the twentieth and early twenty-first centuries is more about ourselves than about benefits for future generations. As Lowenthal (2005) indicated, the existing concern for the future in heritage management has been "a matter of enriching our own life with depth and purpose." As mortal human beings, we pursue meaningful purposes that survive ourselves. Arguably, the widespread desire to protect and preserve heritage is nothing but one outcome of a strong human desire to obtain a sense of purpose by caring for something profound, whether that may be the ozone layer and global climate, homeless people and the fight against poverty, tigers and the protection of biodiversity or Stonehenge, and other cultural heritage sites. We never asked which role we can expect heritage to play in the *actual* future which will differ from the present and thus require new policies and practices.

Looking at the preservation of heritage from this perspective emphasizes its cultural and historical specificity and thus the realization that the current preservation paradigm will not be forever. Future historians and archaeologists, perhaps looking for explanations to the excessive desire to preserve in our age, will be able to draw on a rich material record of reconstructed buildings, restored artefacts, and archived reports (Fairclough 2009). Quite possibly, these future generations will appreciate conserved buildings and sites not so much because it allows them to remember the past (when the structures were built) but because it allows them to remember remembering the past (when the structures were saved). This raises the intriguing and somewhat paradoxical question whether future generations may appreciate the heritage of heritage (Holtorf 2012). Alternatively, as the social anthropologist Tim Ingold (2010) figured in an intriguing future

scenario of the year 2053, archaeologists will appreciate things in terms of persistence rather than preservation. Persistent things originate continuously and like natural processes they carry on growing or decaying. By then, heritage experts no longer take for granted that remains of the past are inherently valuable and deserve to be maintained in perpetuity. There will be no need to "preserve the past for the future" anymore.

Preserving Heritage: The Role of the Media

Christopher R. Eck
Air National Guard, Camp Springs, MD, USA

Introduction

Ever since the modern science of archaeology began to develop from its earlier antiquarianism, there has been a role for the media – from book publishing to newspaper journalism's coverage of discoveries to the depiction of archaeology in various visual arts – in shaping both the profession's and the public's awareness and desire to preserve the world's archaeological and cultural heritage. Then, beginning in the late nineteenth century, electric media began to more rapidly and widely disseminate information for and about archaeology (particularly the more spectacular finds) first through telegraphs and telephones, then in the twentieth century through movies, radio, and television, and, most recently, through the computer and the Internet.

Presently, archaeologists use all of the various types of artistic, broadcast, electronic, and print media to more widely and rapidly promote the documentation and preservation of the many international cultural heritage sites at risk from neglect, war, vandalism, misuse, land development, agriculture, looting, and artificial and natural alterations and disasters. Archaeologists have consistently adapted to the introduction of new technologies that have applications to help better advance the study and preservation of the world's

heritage sites. Most recently, the use of "social media" – whereby usually small amounts of information on a variety of topics are shared and disseminated quickly through the electronically linked networks of persons using computers, mobile telephones, and other devices with Internet accessibility – provides a new arena for the evolution of the role of the media in assisting the archaeological community in calling the public's attention to the need to understand, conserve, protect, and document the cultural heritage of the people of all nations.

Definition

The role of the media in preserving cultural heritage can be defined as the use of the full range of journalistic, artistic, print, electronic, and broadcast mass communications to inform the professional archaeological community and the general public on the many methods, activities, and plans for encouraging the understanding, protection, conservation, and documentation of the world's archaeological, historical, artistic, and cultural patrimony for the present and future generations.

Historical Background

The first mass communication medium to be used to promote the preservation and understanding of archaeological and cultural heritage was *book publishing*. For instance, as early as 1482, the work *Romae instauratae* ("Rome Restored"), written by the Italian humanist, historian, and "father of archaeology," Flavio Biondo (1388–1463), was the first book on archaeology to be published on the recently invented *printing press with movable type*. This and other works of Biondo's were printed posthumously by his sons less than 20 years after the German inventor Johannes Gutenberg's printing press was first brought into Italy around 1464 and only about 30 years after Gutenberg first prepared his famed eponymous bible using this device.

In the Renaissance, encouraged by the more widespread dissemination of information – particularly a better knowledge of classical antiquity based in large part by the revolution in mass book printing and book selling – scholars such as the English antiquarian and historian William Camden (1551–1623) undertook writing about the ancient histories of their own nations, especially those places that were once linked to the Roman Empire. In his work, *Britannia* – first published in 1588 in Latin and then in subsequent English editions – Camden recognized the association between archaeological finds (particularly ancient coins) and an area's history. In writing on the history of Kent, for example, he was observant in noting the existence of crop marks in fields upon the former locations of buildings and the coins that turned up in plowing:

> When the *Romans* govern'd here, the City was exceedingly Famous; from thence they commonly set sail from *Britain* to the Continent: But now Age has eras'd the very Tracts of it, and to teach us, that Cities die as well as Men, it is at this Day a Common Field, wherein, when the Corn is grown up, one may observe the Draughts of Streets crossing one another, for where they gone, the Corn is thinner. Nothing of the City now remains, but some ruinous Walls of rough Flints, and long *British* Bricks, the Cement of which is as hard as Stone. But the Plot of the City, now plough'd, has often cast up the Marks of its Antiquity, Gold and Silver Coins of the *Romans*. . . (Camden 1701).

Notably, despite recognizing the significance of these sites and their relationship to the past, Camden does not advocate for their preservation in his writing.

With a palpable interest being encouraged through literature in understanding the ancient past, more people began visiting the sites described in the various published histories – the early modern version of what we call today "cultural tourism." Artists such as the Venetian Giovanni Battista Piranesi (1720–1778), who had himself been first trained as an architect, began producing for sale to these tourists a series of printed etchings that showed the ancient ruins of Rome. These artistic "views," as they were called, depicted the city's archaeological landmarks and helped to popularize the knowledge of archaeology to both locals and visitors alike and to further spur a revival in the use of the

classical orders in Western architecture based upon these images and the increased appreciation of these ruins.

Toward the end of the eighteenth century, the first scientific excavation of an archaeological site was undertaken by the American politician, scientist, and Enlightenment polymath Thomas Jefferson. Described in his now renowned book, *Notes on the State of Virginia*, which was first published in French in 1785 and then in English in 1787, Jefferson fairly systematically undertook a stratigraphic excavation of a Native American burial mound (or barrow) in 1783, correctly hypothesizing that the origins of the mounds were aboriginal in origin and of great age. Importantly, Jefferson also set the standard for publishing his findings relatively quickly (Jefferson 1787).

A few years after Jefferson's book was published, the American naturalist and scientist *William Bartram* (1739–1823) – a close friend of Jefferson – published his own keen observations of ancient Native American archaeological sites based upon his travels throughout the American Southeast in the mid-1770s. Bartram's publication of his famous book, *Travels through North and South Carolina, Georgia, East and West Florida*, in Philadelphia in 1791 led to a further increased awareness of the antiquity of aboriginal culture in North America from comments laced throughout his famous work, such as his observation that "amongst the shells of the conical mounds, fragments of earthen vessels, and of other utensils, the manufacture of the ancients . . ." (Bartram 1791).

These books, along with writings published by a number of other eighteenth- and early nineteenth-century scholars in Europe, such as the Germans Johann Winckelmann (1717–1768) and Alexander von Humboldt (1769–1859), helped to construct an intellectual foundation for a more widespread appreciation for the artistry, diversity, and antiquity of human cultures in the Old and New Worlds. Then, combining the media of book publishing and fine art printing, a multitude of richly illustrated multivolume books – such as von Humboldt's *Voyage aux regions equinoxiales du Nouveau Continent* (Paris 1807), the French Commission des Sciences et des Arts' *Description de l'Egypte* (Paris 1809), and, later, the acclaimed *Incidents of Travel in Central America, Chiapas and Yucatan* (New York 1841) by the American diplomat, explorer, and writer John Lloyd Stephens (1805–1852) as illustrated by English artist and architect Frederick Catherwood (1799–1854) – began to regularly appear to the delight and astonishment of the reading public with visually informed descriptions of the archaeological wonders of the world's past civilizations.

The efforts of those studying archaeology and history in Europe and the Americas, however, did not prevent the widespread destruction of many of these sites within their own communities. There remained the need to develop and inculcate a widespread *conservation ethic* in societies as a whole, to develop an appreciation for what American preservationist and architectural historian James Marston Fitch (1909–2000) would later call – in our modern age of industrialized duplication and facsimilitude – the need to "preserve the prototype" (Fitch 2001). There was, of course, a bias inherent in much of what was being viewed by those doing the viewing and the studying toward those sites with physical remains that were permanent and monumental which we recognize today that went largely without comment at the time.

For an ethic of heritage preservation to diffuse and become instilled in societies across the world, there was required a medium of communication that could carry its *ideas* and the *idioms*. Also, at a time with high rates of illiteracy and poverty, even for those people who could read, the common media for transmitting ideas of heritage conservation – books and art – were expensive and intellectually detached from the lives of most people. Other avenues of instruction were needed.

One development was the recognition of the growing public interest and comprehension of archaeology from book publishing and artistic printing, particularly among the growing mercantile classes with some measure of disposable income and education. Hence, the establishment in the eighteenth century of the modern *museum* provided a forum for the public to view and discuss the exhibits of objects of cultural and natural heritage in their most tangible form. For instance,

William Bartram's Philadelphian friend, the artist and naturalist Charles Willson Peale (1741–1827), established his *Philadelphia Museum* as North America's first public museums in 1786. Though other museums – such as the Vatican Museums in Rome and the Ashmolean Museum in Oxford – had opened to limited numbers of the social elite ("the public") in the fifteenth to seventeenth centuries, Peale's museum was envisioned as a more truly democratic institution, open to people of all classes of society, as most museums are throughout the world today.

Peale conceived of his museum's spaces – such as the "Antique Room" along with other galleries that displayed artifacts and ethnographic objects from throughout the Americas, the Pacific, East Asia, and Europe that were tangibly and closely present to visitors – in a way that most people were previously unable to experience. A widely recognizable image is Peale's 1822 self-portrait painting, *The Artist in His Museum*, in which he is depicted lifting the curtain to reveal to the viewer a space of row upon row of his wondrous array of fossils, mounts, objects, and artwork unlike almost anything seen anywhere else in the world up through that time except by a small number of the very rich.

Peale also recognized the power of promoting his museum through the use of *newspapers*. Long one of the most influential of the communication media, newspapers were the ubiquitous lifeblood of information in the mercantile ports, city streets, and country shops of the Americas and Europe in the eighteenth and nineteenth centuries. Peale's desire was that his museum would serve to educate and entertain both rich and poor about the diversity of the world's cultural and natural heritage (Hansen 2008), and newspapers made it affordable to promote this idea to a mass audience through their articles and advertisements.

Print journalism became one of the more vital media in the early efforts for decrying the destruction of cultural heritage and in the advocacy for the preservation of sites. Notably, one of the first heritage landmarks to be saved from destruction was Pennsylvania's Old State House, best known now as *Independence Hall* and the site of the signing of the Declaration of Independence in 1776 and other momentous events in America's early national history. Transferred from state custody to that of the City of Philadelphia in 1812, the city had proposed demolishing the building and selling off the land for development, but a public outcry to such an action led by the community's newspapers succeeded in ensuring the preservation the building in 1816 (Nash 2006). Notably, Peale's museum was a tenant of the building's second floor.

Another significant development that aided in the development of media networks for the spread of information – regarding cultural heritage or any other subject through the mail and newspapers – was the creation of national *postal services* with uniform, affordable mail delivery rates and the coeval creation of reliable post roads throughout these countries. Thus, the formation of national postal service and post road systems, along with the technological development of steamboats and railroads in the early nineteenth century, created *national transportation and communication networks* that facilitated the ability to send current news, information, and publications to people throughout the nations of Europe and the Americas and elsewhere which coincided with the growing awareness of preserving heritage sites and the creation of national identities. For example, the national postal and transportation system created in the United States allowed Ann Pamela Cunningham (1816–1875), the founder of the Mount Vernon Ladies' Association, to successfully manage a network of supporters across America for soliciting contributions for the purchase and preservation of George Washington's former estate of *Mount Vernon* in Virginia from 1853 to1858 (Murtagh 2006). Her work is considered a watershed event in the preservation movement in North America.

As other technological developments related to communications media occurred, these were also incorporated into the archaeological and heritage conservation tool kit. The advent of *photography* in 1826, and its subsequent improvement by the French photographic pioneer Louis-Jacques-Mande Daguerre (1787–1851) in 1839, permitted

detailed imagery of actual archaeological sites to be composed and transmitted more quickly and accurately than drawings or paintings to persons anywhere. In producing these early images, it was not uncommon to photograph a scene that contained a site of archaeological interest which was incidental to the original purpose of the photograph. Many of these early pictures document in great detail the contemporary surroundings and conditions of individual landmarks and remain of great interest to archaeologists, architectural historians, and others interested in the details of a site. A historic image of a landmark can be juxtaposed with a modern photograph – such as a picture of the Roman Colosseum in the 1860s and an image of the same view in the present – to gain a detailed perspective and insight into the changes that have taken place over time (D'Orazio 2004).

The use of photography as a medium of communication within archaeology coevolved with the discipline in the nineteenth century as archaeologists sought to use images to convey the sense of place of the sites they were studying and to document the artifacts that were recovered. During this period, the French army officer, travel writer, and photographer Maxime du Camp (1822–1894) was among the first photographers to incorporate images of archaeological sites – such as those in Egypt – into books, such as his *Égypte, Nubie, Palestine et Syrie* (1852), which further whetted the popular interest in the past using the new medium. The Greek photographer Dimitrios Constantinou (fl. 1850s–1870s), better known in English as "Dimitris Constantine," is recognized as the second professional photographer in Greece and whose work stands out for being conducted specifically for the Greek Archaeological Society in recording excavations and archaeological sites, as well as for its quality.

The German architect and archaeologist Ernst Emil Herzfeld (1879–1948) was among the first professional archaeologists to systematically use photography as a tool of study and documentation. Herzfeld participated in and later led expeditions in Iraq, Iran, Syria, and Turkey from 1903 to 1934, and his photographs of early western Asian civilizations richly inform his writings and those of his German friend and colleague Friedrich Sarre (1865–1945), director of the Islamic Museum in Berlin (Bloom and Blair 2009). His extensive photographic collection of nearly 4,000 glass negatives from his work forms part of the "Ernst Herzfeld Papers, 1899–1962" of the Freer Gallery of Art and Arthur M. Sackler Gallery Archives of the Smithsonian Institution in Washington.

One of the earliest and best known deliberate uses of photography to document and exploit the popular image of the "romance" of exotic archaeological excavations was by the American archaeologist and explorer Hiram Bingham (1875–1956). In his 1911 expedition to the "Lost City of the Incas," Macchu Picchu, while high in the Peruvian Andes he wrote, "Would anyone believe what I had found? Fortunately, in this land where accuracy in reporting what one has seen is not a prevailing characteristic of travelers, I had a good camera and the sun was shining" (Bingham 1996).

Following photography, the ability to quickly share information about a major discovery or even plan or maintain the mundane logistics of a long-distance expedition to an archaeological site was aided greatly by the independent development of the first commercially practical application of the *electrical telegraph* in both Britain and the United States in 1837. Several decades later, British architect and archaeologist John Turtle Wood (1821–1890), for example, summarized how telegraphic communications could combine with the other technological innovations of the time to aid him in his excavations at Ephesus. Although appended with a personal critique of the waste of resources on less important subjects than archaeology – a refrain still common today in the field – he wrote:

> The explorers of half a century ago had neither steam to convey them to distant coasts, nor the practical knowledge of archaeology which we now possess to guide their researches, nor photographers to record their discoveries, nor an electric telegraph wherewith to maintain communication with a distant base of operations. We, with all of these appliances, and with boundless wealth at the command of individuals, if not of governments, grudge to these great enterprises the money which is daily wasted on trivial and ignoble objects (Wood 1877).

Although telegraph communications would be supplemented by the end of the nineteenth century by the *telephone* and eventually replaced by it in the twentieth century, these two media exponentially increased the ability of archaeologists to communicate their work both within and without the profession.

By the late nineteenth century, another communication medium had developed and was stirring the popular imagination regarding archaeology and heritage sites around the world: the *novel*. One of the most influential novelists was the English author Sir Henry Rider Haggard (1856–1925), creator of the Allan Quatermain character and considered the first to write in the "Lost World" genre of fiction. His first book, *King Solomon's Mines* (London 1885), was inspired by both Robert Louis Stevenson's *Treasure Island* (London 1883) and by the archaeological discoveries of the day. The character of the dashing explorer-archaeologist, itself inspired by a number of seemingly larger-than-life figures of the nineteenth century – such as the Italian adventurer in Egypt Giovanni Battista Belzoni (1778–1823) and the British explorer, archaeologist, and statesman Sir Austen Henry Layard (1817–1894) – would itself further inspire future generations of students of archaeology and even more fictional characters in both twentieth century literature, such as in the writings of English author Agatha Christie (1890–1976), herself married to an archaeologist, but especially in the new cinematic art of *motion pictures*.

Movies have arguably been the medium that has had the most influence on the popular view of archaeology and cultural heritage. Among the first *silent films* to depict archaeologists – particularly those afflicted with tomb curses and avenging mummies – were *The Vengeance of Egypt* (French, 1912), *When Soul Meets Soul* (American, 1912), and *The Wraith of the Tomb* (British, 1915), among others. Subsequent *talking films* have continued using archaeology as a plot device for cinematic adventure up to the present, from *The Mummy* (1932) to the Indiana Jones character films, beginning with *Raiders of the Lost Ark* (1981) to *National Treasure* (2004) and others. Apparently, after more than a century's worth of books, news articles, artwork, museum exhibitions, and novels, a near universal understanding of the intersection between archaeology and adventure has been created in the popular imagination.

This is not to say that archaeologists themselves have not used the medium of film for more academic purposes. Archaeologists began capturing their field excavations on *documentary films* as early as the 1920s, but the content of these first works was haphazard and the quality often uneven. In 1937, the *Tennessee Valley Authority* in the United States produced a film, *Shell Mounds in the Tennessee Valley*, which was among the first to have a soundtrack and set a high standard for future documentary films for the public. Since that time, with the cost of filming over the years steadily declining and, most recently, the appearance of relatively simple and inexpensive digital handheld cameras, the ability to film excavations and document sites is quite literally within the grasp of virtually any project team to bring its work to the public's attention.

Documentary filming in some contexts, however, remains a significant challenge, particularly in the realm of submerged archaeological sites. Among the earliest underwater archaeology films was *Epaves* ("Shipwrecks," 1943) by the French explorer, marine conservationist and filmmaker Jacques-Yves Cousteau (1910–1997), many of whose later films were made for broadcast for *television*.

In the case of life imitating art, both Cousteau and the American marine geologist and archaeological oceanographer Robert Duane Ballard (b. 1942) are said to have been inspired by the novel *20,000 Leagues Under the* Sea (Paris 1870) by French author Jules Verne (1828–1905). In 1985, in his own version of Verne's fictional submarine, *Nautilus*, Ballard discovered the site of the famed wreck of the *HMS Titanic*. The disclosure of the wreck's location – from which Ballard refused to remove anything from because of his belief that it should be protected as a maritime gravesite – led to it being salvaged by a for-profit the year after Ballard broadcast footage of the discovery to the awe of millions of television viewers in 1986 (Ballard 2010). Then, coming

full circle, a fictional maritime archaeological discovery of the wreck was later depicted in the immensely successful film *Titanic* (1997).

In the second half of the twentieth century, imagery and sounds related to archaeological endeavors have been regularly broadcast by *radio* and *television* media. Among the most important and prolific promoters of archaeology through the broadcast media (as well as in print) was the Scottish military officer and archaeologist Sir Mortimer Wheeler (1890–1976) and the Welsh archaeologist Glyn Daniel (1914–1986), both of whom often worked closely together on BBC radio and television programs in the 1950s. In fact, Wheeler became "Television Personality of the Year" in 1954 on the BBC (Noel Hume 2010).

In recent years, archaeology-themed documentaries have become a staple of television. They have, however, been criticized for presenting content that is not very relevant to the audience to which they are being shown. An Australian study showed that most of the content for local audiences was produced by foreign production companies (such as the BBC) about sites in other countries and were not reflective of the diversity of their audiences (Nichols 2006).

These documentaries, however, are not to be confused with the *reality television* genre that has arisen in recent years. Shows such as *Extreme Archaeology* and *Digging for the Truth* – which focus more on attractive participants (many not even trained in archaeology) in contrived, sensationalized "searches" for information – are becoming ever more commonplace as pay-television broadcasting seeks more "content" to fill its "air time" (Nicholas 2005).

Nonetheless, the prints, paintings, photographs, films, and television imagery of archaeology and heritage sites of the last 200 years have thoroughly prepared the groundwork for the completely visually oriented society that exists today. Contemporary popular culture is infused with and accepting of imagery of past cultures as a result of the role of mass media. Combined with this, the technological and information revolution brought about since the 1960s in the use of *computers* and the role of the *Internet* over the last 20 years has brought information about archaeology and cultural heritage – in all forms, such as in advertising and *computer games* – to homes in every part of both the developed and developing world. The mass media has made the imagery of archaeology, through its replication and application in all forms, completely ubiquitous.

The use of computers and the Internet has greatly expanded the reach of all media and the ability of information on archaeological site preservation to reach a variety of audiences. Researchers and the public can readily access books, articles, and studies online from the comfort of their own homes. Publications and archival documents and photographs once available from a small number of research collections and usually only used or visited by a small number of researchers are now regularly being reproduced in a digital format and made available to anyone. *Aerial photography* and *satellite imagery*, both long part of the archaeological toolkit for teasing out the possible locations of sites, are now openly viewed on websites offering free map services to the public. In Ireland, as elsewhere, the use of computer-aided Internet tools such as *Google Earth* has made possible the finding of archaeological sites by both professional archaeologists and the public alike (Darby 2007).

Additionally, among the field of archaeology's oldest and most effective forms of media are *magazines* and *scholarly journals*. Journals and magazines, like their cousin the newspaper, have been around quite a long time with some of the earliest that were devoted exclusively to archaeology and heritage arising as publications of local history and antiquarian societies formed in the mid-eighteenth through nineteenth centuries, such as the Society of Antiquaries' *Archaeologia* (1770), the British Archaeological Association's *The Archaeological Journal* (1845), and the Norfolk and Norwich Archaeological Society's *Norfolk Archaeology* (1847) in Britain. The enormous popularity of both the scientific journal and popular magazine format – often accompanied by illustrations, photographs, maps, and figures – is attested by the hundreds of publications produced around the world in most major languages that can inform both professional and nonprofessional

alike of current developments in the field, work that is the culmination of years of research and other news of note, including training and educational conferences.

A clear consequence of the mass media's promotion of archaeology is the greater sense of shared history and interest in cultures that now exists across the globe. The discovery of a significant site in a remote part of eastern Asia or the Australian outback is nearly as likely to make the headlines in Rome or New York as one found in more familiar places, such as Europe, Mexico, or the Near East. The increased attention provided to the preservation of heritage lends widespread appreciation and support for the use of national parks and local landmarks and museums. There is recognition among archaeologists and other preservationists of the professional need and responsibility to better engage the public to achieve the support needed for public funding of research and site protection, to instill a cultural desire to preserve cultural heritage, and to prevent depredations, looting, and vandalism to archaeological sites and other monuments. A 1999 survey in Canada shows that the public is very interested in archaeology and is supportive of preserving heritage sites but has a limited understanding of archaeological interpretation and heritage site protection laws (Pokotylo and Guppy 1999).

Key Issues/Current Debates

Over the past century and still in the present, there exists a debate within archaeology over the depiction of both archaeologists and the field of archaeology in the media. This is not a new debate: it is one that pits the common conception of the field as filled with romance and adventure against that of archaeologist as out-of-touch scientists who are absentmindedly lost in the past. It is a product of two centuries of conflicting media exposure, both fictional and not.

Addressing this is largely a matter of public relations and public archaeology. Unfortunately, there has been very little written in the professional journals about conducting "good PR" that helps to dispel misconceptions of the field and instill a better understanding of the profession in preserving shared cultural heritage with rare exception. McManamon (1991) challenged archaeologists more than 20 years ago to do a better job of engaging and educating the public about the goals and roles of archaeology in preserving heritage.

The ease of access to heritage sites and the information about them also has a more troubling aspect. Archaeological site looting, or pot-hunting as it has long been called, has long been a problem for the field. But the same modern tools, equipment, and access to information that have made work for professional archaeologists better have also made it easier for looters to damage sites as well, usually for profit. The misunderstanding fostered by "reality" television shows has not helped distinguish professional archaeologists from those that are little more than looters. So, amid protests by professionals, it was not unexpected that recent "reality" television programming in the United States, such as the National Geographic Channel's *Diggers* or Spike TV's *American Digger*, disregards the contextual, informational, and conservation goals of archaeology and, instead, focuses narrowly on the potential monetary reward of site destruction and the "adventure" of the find (Kloor 2012). The field of archaeology – keeping in mind its ethical responsibilities to its work and the conservation of sites – has a great opportunity here to do better and offer better programming that is engaging, audience focused, and accurate in its scope.

All of this serves to illustrate that although public-focused archaeology that relies on the media to assist in presenting its message has expanded greatly in much of the developed world, much more still needs to be done and it is a continual process of effort. One example of the successful establishment of a public program is in Florida, where the state legislature established the Florida Public Archaeology Network (FPAN) in 2004 with a headquarters and eight regional offices staffed by professionals who develop local public programming and assist local governments.

Just as the public has found great benefit in having better digital access to formerly difficult to

obtain information, there is still a great need for the profession to make use of the millions of archive records, photographs, and artifacts from prior excavations of the past 200 years. The diminishing numbers of certain types of cultural sites due to rapid urbanization in many parts of the world demand that archaeologists use the media available to conserve finite cultural and financial resources.

One of the benefits of the digitization projects is the great availability of digital resources, both in finding specific collections and in accessing difficult-to-find information. As the use of photography in archaeological excavation and for the documentation of sites was well established by the first half of the twentieth century, there are vastly underutilized photographic archives in universities and museum holdings around the world. Yet, there remains a great need to catalog and make accessible these valuable resources, particularly in countries and places where resources are scarce. For example, the Smithsonian has recently undertaken efforts to digitize the thousands of images created by Herzfeld in his work in the Near East, but thousands upon thousands of photographs from other sites – such as those from nearly a decade of work at Dura-Europos in Syria from 1928 to 1937 – remain largely unpublished and inaccessible (Baird 2011).

International Perspectives

Given the recent conflicts in Syria and the overthrow of governments in North Africa, coupled with the current political instability in the Near East where archaeological tremendous study has taken place for generations, the preserved collections that exist outside these areas take on an added and special importance to both scholars and the public for understanding human history and culture.

Training programs for archaeological and heritage professionals have been sponsored by institutions in North America and Europe for some time in these areas, to better establish a cadre of local professionals that are part of the local community. Foreign government agencies, such as the US Agency for International Development (USAID), recognize that providing local communities with stable sources of income and education helps deter looting, promotes understanding of indigenous cultures among both locals and visitors, and provides a source of income for cultural tourism (Amin and Jones 2008). However, recent events in the civil unrest for the governments of Libya, Egypt, and Syria have put such programs on hold, have led to reports of the damage to or looting of sites, and undermine or eliminate progress in heritage conservation that has taken years to establish.

Another important development is the recognition throughout the profession worldwide that there is a need to better and more formally teach archaeological practitioners how to communicate to divergent public audiences through the audio-visual media. At the University College London's Institute for Archaeology, for example, there has recently been established the *Centre for Audio-Visual Study and Practice in Archaeology* (CASPAR) which seeks to "promote research into the relationship between audio-visual media and archaeology" and to "enable inventive and creative use of audio-visual media by archaeologists" among it several aims.

To spread such information, many of the world's national and international non-governmental heritage preservation organizations, such as the *International Council on Monuments and Sites* (ICOMOS), rely heavily on the use of electronic media to quickly and cost-effectively reach local and international audiences. The efficiency of the new Internet and social media in reaching large numbers of archaeological and other heritage professionals, interested members of the public, and elected decision makers has made their incorporation into most NGOs communications strategies a prerequisite. For instance, when a rebel military force overran the ancient scholarly city of *Timbuktu* in Mali in the spring of 2012, the international archaeological community and relief NGOs quickly became aware of the threats to the city's ancient mud-brick shrines, libraries, and other structures within days as computer and mobile telecommunication devices were able to send

messages, photographs, and video images out of the city despite its occupation.

Similarly, a number of governmental organizations, such as the US military's *Joint Prisoner of War/Missing in Action Accounting Command* (JPAC) which is based in Hawaii, have also taken to the use of the new media formats to disseminate information about their missions. Composed of interdisciplinary teams of archaeologists, historians, forensic anthropologists, and active-duty military, JPAC sends its members around the world to recover the remains of military service members from sites where they died overseas in battle, but who were never brought back for burial in the United States. JPAC works closely with foreign governments in its fieldwork in other countries and communicates the results of its activities to the public through an effectual media relations program of emails, blog posts, web pages, video links, and other electronic and social media formats that builds support for its work.

As the world becomes increasingly "smaller" through the use of communications media, the opportunities to better understand the archaeology of cultures, such as China, which have heretofore been largely inward looking, become markedly improved. There is a great need in the developed world to better understand the developing world, as the issues of one nation rarely stay confined within its actual – or even "digital" – borders any longer.

Future Directions

Understanding the role that communications media holds in modern society is crucial and unavoidable in modern archaeology and heritage site preservation. Archaeologists and preservationists at all levels must develop a keen awareness of all media in developing plans for the study and conservation of sites and expect to be engaged with the public's appreciation for the past and heritage conservation. Professional archaeologists – who have readily adopted new technologies for communicating their work throughout the history of archaeology – have been much slower to recognize the necessity of public engagement with the field. The rapidity and ubiquity of communications media require the profession to see the great opportunity that now exists to dispel misconceptions about the field, to readily involve the interested public about its work, to lobby for changes in legislation for the better protection and conservation of sites and artifacts from illegal looting or trade, and to inspire people of all backgrounds to use the communications media at their disposal to take an active role in preserving the world's shared cultural heritage.

Preucel, Robert W.

Alexander A. Bauer
Department of Anthropology, Queens College, CUNY, Flushing, NY, USA

Basic Biographical Information

Robert W. Preucel (Fig. 1) is an anthropological archaeologist who is a leading voice in many areas of archaeological theory and practice, from Native North American archaeology to problems of philosophy and epistemology, to the engagement with Native communities in archaeological practice and academia more generally. He received his B.A. in anthropology in 1978 from the University of Pennsylvania. Having interests in both North American and Near Eastern archaeology, Preucel subsequently took a Master's degree (1979) at the University of Chicago where he studied at the Oriental Institute. While at Chicago, he became interested in archaeological method and theory, in particular processual archaeology, and so from there embarked on a Ph.D. (1988) in archaeology at UCLA, where he studied processualist methods and Puebloan archaeology under the guidance of James N. Hill.

Preucel, Robert W., Fig. 1 Robert Preucel

After graduating from UCLA, Preucel was awarded a postdoctoral fellowship at the Center for Archaeological Investigations at Southern Illinois University, Carbondale (1988–89), where he organized a conference on the Processual-Postprocessual debate (Preucel 1991a). In 1989, he joined the faculty of Harvard University as an Assistant Professor of Anthropology and Assistant Curator of North America at the Peabody Museum. He was later promoted as Associate Professor and Associate Curator (1993–1995). In 1995, he returned to the University of Pennsylvania, this time as Associate Professor of Anthropology and Associate Curator of the American Section of the University Museum. He was promoted to Professorship in 2007 and two years later made the Sally and Alvin V. Shoemaker Professor of Anthropology and the Gregory Annenberg Weingarten Curator-in-Charge of the American Section of the University Museum. He served as the Chair of the Department (2009–2012) and the Director of the Center for Native American Studies (2007–2013). In 2013, he was appointed as the Director of the Haffenreffer Museum of Anthropology and Professor of Anthropology at Brown University.

Major Accomplishments

Robert Preucel has made and continues to make significant contributions to several different arenas of scholarship and practice, most notably archaeological theory, Puebloan archaeology, and engagement with Native American communities. His interest in archaeological theory and epistemology drew him first to study Processual approaches and then consider its critiques over the course of his doctoral studies. While a graduate student, he coauthored an important essay on those debates with Tim Earle entitled "Processual Archaeology and the Radical Critique" (Earle and Preucel 1987). Subsequently, the conference he organized as a postdoctoral scholar at Carbondale resulted in one of the most important volumes on this debate (Preucel 1991a), with his essay "The Philosophy of Archaeology" (Preucel 1991b) remaining a key distillation of the core components of archaeological reasoning. In 1996, he collaborated with Ian Hodder to write the first incarnation of *Contemporary Archaeology in Theory* (Preucel and Hodder 1996), a reader on archaeological method and theory that was as valuable for the short introductory essays that Preucel and Hodder wrote as for the readings it contained.

During his time at Harvard, Preucel had the opportunity to expand his interest in philosophy through interaction with colleagues such as Terry Deacon, David Rudner, and Rosemary Joyce, and at the Peirce Sesquicentennial International Congress at Harvard University in 1989, he first encountered the semiotic writings of American philosopher Charles Sanders Peirce, whose work focused on the production of meaning and the logic of inferences about the world. Preucel felt that Peirce's model, notably being non-foundational and an alternative to both positivist and non-positivist approaches, might be especially productive for archaeological inquiry and its problem of verifiability. He laid out and tested this framework in a series of essays (Preucel and Bauer 2001; Capone and Preucel 2002; Ferguson and Preucel 2005), culminating in his 2006 book *Archaeological Semiotics* (Preucel 2006). Preucel continues to

explore Peirce's ideas and in particular the utility of pragmatism generally as a way to produce a more inclusive and ethically engaged archaeology (Preucel and Mrozowski 2010), particularly with respect to bridging Native and indigenous ways of knowing the world with Western scientific approaches.

Preucel has had a long-standing research engagement with the Puebloan communities of the southwest United States. Since 1995, he has collaborated with Cochiti Pueblo in New Mexico on the Kotyiti Research Project, a multidimensional study of an ancestral Cochiti village from the time of the Pueblo Revolt, incorporating archaeological survey, mapping, oral history study and interviews with elders from Cochiti, and museum and historical analysis. This project seeks to address questions about the links between past and present identities as well as what constitutes responsible and ethical collaboration. Engagement with the Cochiti community is a central pillar of this project and it includes the active participation of Cochiti elders as well as youth through an internship program. Both in the Kotyiti Research Project and in his collaborations with T.J. Ferguson and his former students, Preucel has sought to understand the ways in which Puebloan identity and ideology was expressed materially during the period of the Pueblo Revolt and since (Preucel 2002, 2006; Liebmann and Preucel 2007).

Preucel's involvement with Native Americans and concerns about ethical academic practice have not been limited to his own research agendas, but have guided much of his work at the University of Pennsylvania Museum and in the University as a whole. At the University Museum, he has facilitated collaborative relationships with many Native American communities, and has provided important examples of how NAGPRA works at its best. He has also been active in increasing Native American participation and enrollment at Penn through serving on university-wide committees on diversity outreach, minority recruitment, and pushing to establish the Center for Native American Studies. Through this work, and in complement to his academic research goals, Preucel has sought to increase the visibility of Native Americans in academia and raise the profile of topical concerns of Native peoples more generally.

Privatization, Public-Private Partnerships, and Innovative Financing for Archaeology and Heritage

Peter G. Gould
Penn Cultural Heritage Center, University of Pennsylvania Museum of Archaeology and Anthropology, Philadelphia, PA, USA

Introduction

Managing and maintaining cultural heritage is expensive and growing more so. A common perception encouraged by economists is that cultural resources are "public goods" that merit funding support from governments. In practice, the role of governments in heritage management has been diminishing in much of the world, even as the drivers of demand for robust heritage management – migrations to urban areas, infrastructure construction, tourism, and the like – progress unabated. The matter of who can and should pay for heritage management, and how that financing should be generated, is a matter of practical concern within the discipline. Government funders simply do not have the capacity to serve fully the needs of the heritage management sector. Increasingly, and despite misgivings among heritage professionals, private sector actors are assuming leading roles in heritage management. This entry will address the issues arising from the challenge of financing archaeology and cultural heritage at a time when heritage management has been transformed into a global commercial endeavor and popular activity that is inextricably implicated with capitalist development and the private sector.

To be clear from the outset, the subject matter of this entry is diverse and nomenclature is problematic. The entry addresses the role of private sector financing, in various forms, across a broad swathe of heritage-related activity. For simplicity, albeit perhaps unconventionally, the term "heritage management" will be used throughout to encompass academic archaeological field research and conservation; the programming, curation, and management of museums; work in commercial enterprises by professional archaeologists and other specialists; and the activities of conservation specialists in urban redevelopment. The entry will present an overview of the privatization phenomenon in heritage management from a theoretical, historical, and international perspective. The issues are complex and nuanced, and the objective here is to frame those issues for the uninitiated reader and point them and others toward relevant resources and scholarship. Because academic research into these matters is limited, this entry also may suggest an agenda for future research and exploration into private sector involvement in archaeology and cultural heritage.

Definition

Privatization may best be defined by what it is not: it is the absence of complete government control and responsibility for a sphere of public activity.

Instead, the provision of some or all of an activity ordinarily assigned to a government agency becomes the responsibility of a non-governmental entity. Although privatization has a long history, more recent privatization trends reflect neoliberal efforts to reverse the accumulation of responsibilities in the hands of governments, especially national governments.

Privatization has been employed across the full range of government functions, from national defense to health care and social services, road building to water supplies, public transportation to the management of prisons (Farquharson et al. 2011; Yescombe 2007). Privatization takes a variety of forms (Hodge and Greve 2016; Linder 1999), including outright divestiture of government operations, transformation of state organizations into independent or quasi-independent structures, agency agreements in which private actors substitute for government bureaucracies without taking ownership, outsourcing of specialized functions to private contractors, the use of volunteers to perform work once performed by public employees, or simply the use of private financing, including charitable gifts, user fees, or revenues from ancillary businesses. In some countries, nonprofit organizations and "social enterprises" deliver a variety of social and cultural services, often partially facilitated by public financial support. A variety of incentives encourage private commercial development in most countries. Depending on the country, these policies are variously labelled as privatization, *désétatisation*, autonomization, or more commonly public-private partnerships (PPPs). PPPs are in particular vogue at the moment, though their forms are so varied and their results so controversial that generalizations about their consequences are highly problematic.

By whatever name and in whatever form, privatization is deeply embedded in cultural heritage practice (Macdonald and Cheong 2014; Boorsma et al. 1998). Privatized heritage management is evident in the global commercial cultural heritage management (CHM) sector that delivers contract excavation and consulting services to contractors and government agencies. Nonprofit organizations that rely primarily on earned revenues and philanthropy manage the majority of cultural institutions in the United States and the United Kingdom and increasing numbers throughout Europe and elsewhere. Particularly at larger museums and heritage sites, at least some business operations such as retail shops, food services, or security are routinely outsourced to private contractors. NGOs work internationally to support community development and archaeological resource preservation, while many government-owned museums that receive government grants also solicit private philanthropic support. Private developers and some non-governmental organizations (NGOs) are leading the resurrection of urban cores and historical structures. Although rare, even a few archaeological sites have been turned over to public-private ventures or regional or local governments. Public archaeology programs and field schools, even if directed by academic scholars, increasingly are managed by private operations. There is, in other words, no escape from the private sector in heritage management.

Historical Background

Private financing and management of public services originated with canals constructed in France in the seventeenth century, with bridge and road construction in the United Kingdom during the eighteenth and nineteenth centuries, and with nineteenth century in projects like toll roads or the Brooklyn Bridge in the United States (Yescombe 2007, 5). Indeed, private parties have been suppliers of goods, services, and financing to central governments from time immemorial. The most recent drive toward privatization, however, has its roots in the late twentieth century, especially in the United States and the United Kingdom in the 1980s, when hyperinflation and recession brought to power neoliberal skeptics who questioned the capacity of governments and favored market-based solutions to public challenges. The effort, which came to be known as the "New Public Management," espoused holding government agencies accountable for results and transferring operational responsibilities to profit-driven, private sector providers (Yescombe 2007; Boorsma et al. 1998).

Promoters of privatization seek to introduce substantive expertise and management experience from the private sector into government agencies thought to be lacking in both and to promote competition among private providers and government agencies. The hope is that competition and private sector expertise will improve service quality, reduce costs to taxpayers, increase program flexibility and innovation, and shift financial and operational risks from taxpayers to private enterprises. Moreover, by relying on specialist providers, proponents argue, governments can exploit those companies' economies of scale and accumulated expertise to obtain better results less expensively. In some countries, particularly the United States and the United Kingdom, there also was a moral overtone: transferring responsibility from national to regional governments, and especially to the private sector, would reduce State power and replace paternalistic government programs with the personal freedom and self-reliance deemed to be ethical goals in neoliberal thought.

Private sector actors long ago stepped in to fill voids in heritage management, starting with privately supported museums and, later, commercial archaeology businesses. Where neoliberal economic and political initiatives took hold in the 1980s, with the United Kingdom as the leading example, politicians restructured government departments and cultural institutions to attract non-government funding and promote efficiency through competition and outsourcing of everything from excavation services to museum management. The need for private resources only intensified after the Great Recession of 2007–2009 as austerity imposed by government action and international creditors pitted funding for cultural activities against urgent and equally imperiled social programs. However, other factors also have been behind the increasing privatization of heritage management. Three examples may illustrate the key forces propelling the private sector role in the field.

- Private philanthropy and nonprofit organizations in the United States play a leading role in financing and performing tasks elsewhere assigned to government agencies. Most of the country's museums and other cultural institutions survive with private sector financing. This model, which grew out of a long tradition in the United States of self-reliance and suspicion of government, has been influential. The legal structures and financial instruments that promote and subsidize non-governmental activity have inspired the emergence of philanthropic trusts, nonprofit organizations, and NGOs around the world. The UK's long history of philanthropy and private activity in the museum sector also has provided alternative models to which countries facing budget austerity have begun to look for ways to fund heritage management.
- An unintended consequence of archaeologists' success in promoting national cultural preservation legislation has been the rapid expansion of the commercial CHM industry. Laws enacted in the United States and Europe in the decades after World War II require preparation of Environmental Impact Assessments that describe impacts on the archaeological record and may require salvage, or rescue, excavation before construction begins. Such laws spread throughout the developed world and have been injected into emerging economies through the policies of the World Bank Group and other development banks (Fleming 2014). The resulting steady and dramatic increase in demand from private contractors and government agencies for salvage excavations soon outstripped the capacity of government agencies or seasonally active academic archaeologists to respond, leading to the emergence of commercial CHM companies (Demoule 2012; Wheaton 2008). Similarly, legislation to list and protect built heritage, from monuments to private homes, has called forth a burgeoning volume of evaluation, conservation, and construction work for the private sector (Macdonald and Cheong 2014). Today, in much of the world, more archaeologists work in the private sector than in government and academic posts.
- The costs to maintain and operate the world's inventory of museums, monuments,

archaeological parks, and heritage sites exceed the fiscal capacity of governments. This is an old problem becoming more severe, as may be seen through the lens of museum commercialization in the United Kingdom (Larkin 2016). British Museum and heritage site retail shops had their beginnings selling collection catalogs to visitors as a part of their educational missions in the nineteenth century, about the same time US museums introduced retail operations. But by the 1960s, before the widespread privatization of the Thatcher era, the UK government already was encouraging museums to increase their revenues from shops, admission fees, and other sources of earned revenue in order to reduce demands for government funding. The United Kingdom's innovations, such as admission fees that shift the cost of operations from the taxpaying public to private consumers (except in national museums), the use of ancillary sources of funding (such as retail shops, wedding rentals, or restaurants), and particularly the sophistication and quality of its merchandising, have been emulated worldwide. Today, some form of gift shop and dining facility, however rudimentary, is standard at any serious museum and many archaeological sites. Even more ambitious UK privatization experiments, discussed below, are now underway in the heritage sector.

These vignettes illustrate three dynamics internal to the sector propelling private sector involvement in heritage management. First, the scale of need in heritage is vast. Nation-building governments and communities desiring to promote local narratives and places have produced heritage sites, national and local museums, and ecomuseums (Davis 2011) throughout the world that depend for survival on local support, user fees, and income earned from tourism. Second, even if "the polluter pays," the large scale of commercial excavation and conservation activity required by law in urban and rural settings necessitates a vibrant commercial CHM sector. Third, heritage services are highly exposed to government budget austerity, making linkages with the private sector essential, either as a source of cost savings or as an alternative source of financing.

These examples also illustrate the carrots (incentives) and the sticks (disincentives) used by governments to promote private sector operational and financial involvement in cultural heritage. Incentives to encourage involvement include cash subsidies, which are widely available from most national and subordinate governments, even in the United States. Tax incentives that encourage charitable contributions, pioneered in the United States, are now established in the United Kingdom and recently expanded in Italy. Museums operating as trusts or nonprofits typically are exempt from income taxation and, in some countries, even public museums or historical sites are permitted to retain their earnings from entry fees, shops, rentals, and other ancillary activities. Governments often offer relief from regulatory restrictions in order to promote development in historically sensitive areas. Disincentives also are important, although their enforcement can be challenging. Steep penalties protect listed buildings and landscapes, compelling owners or developers to spend heavily on archaeological and conservation services, usually from the private sector. Around the world, national legislation requires strict oversight of properties that are owned, financed, or regulated by national governments (although destructive activities on private lands are less well protected in most countries). Development banks also can withhold funding for violations of preservation rules.

Key Issues/Current Debates

Debates continue about the desirability, the feasibility, and the effectiveness of private engagement in heritage management. Concerns about privatization involve five issues: the success of privatization in practice, distributional inequities that arise from privatization, the consequences for employees, the replicability of the US/UK philanthropic funding model, and ethical concerns about archaeology's embrace of capitalism.

On a practical level, public-private partnerships that appropriately allocate costs, benefits,

and risks turn out to be difficult to implement (Hodge and Greve 2016; Farquharson et al. 2011; Yescombe 2007). Government officials with little experience often are pitted against specialist corporate lawyers and executives in negotiations to define the project costs, performance goals and metrics, and risk-allocation mechanisms. Recent assessments of the performance of PPPs generally (European Court of Auditors 2018; Hodge and Greve 2016; Hall 2015) have highlighted the consequences of limited negotiating experience and weak technical capacity in government agencies as a reason for the failure of PPPs to perform as hoped. Moreover, anticipated cost savings and performance improvements in many sectors have not materialized. Avoiding these types of problems and achieving close alignment between public and private partners have been key to successful PPPs in heritage management (Macdonald and Cheong 2014, Part II).

Privatization also is criticized for inequitable distortions of government spending (Hodge and Greve 2016). Contracting companies that have easy political access and economic power, perhaps aligned with bureaucrats pursuing personal priorities, may corrupt the contracting process, which may result in a perverse redistribution of wealth from taxpayers to private companies with no social gain. Even honestly administered PPPs and outsourcing projects may have undesirable distributional consequences. By financing major projects "off-balance sheet," governments may deliver projects faster but are able to mask their true costs to taxpayers by transferring accounting liabilities, but not actual legal or financial risks, to the private sector. The result is both a loss of transparency into the true costs of projects and, potentially, distortion of government spending toward projects that are most easily financed by private enterprises. This "crowding out" may particularly affect cultural heritage-related projects whose smaller and uncertain revenue streams are unappealing to commercial partners and require public support.

Commercial archaeology is a target of criticism for its effects on archaeologists themselves (Hamilakis 2015; Everill 2012). Concerns include relatively low salaries, temporary or seasonal work with little long-term job security, and working conditions that undervalue their expertise. Although commercial archaeologists contend the opposite (Wheaton 2008), critics worry that cost consciousness in commercial CHM impairs the quality of research, increases actual costs, and compromises traditions and local artistic development. Salvage excavations, often focused primarily on documenting findings, have been criticized as atheoretical and scientifically unsound. The difficulty of accessing the "grey literature," where such findings are published, elicits further complaints.

Heritage management by nonprofit organizations has been successful in a few countries, prominently in the United States, Europe, and parts of the Middle East where philanthropic giving is culturally embedded. However, private philanthropy is not a universal value. To some, it is especially suspected if donations are promoted by incentives such as income tax reductions that can be perceived as windfall benefits for the wealthy. As will be discussed below, experiments underway in the United Kingdom and in Italy are testing the degree to which philanthropic models can be exported to other countries, with as yet unknown results.

Finally, some archaeologists, particularly those influenced by Marxist theorizing, raise broader ethical concerns about the interaction of archaeologists and capitalist actors (Hamilakis 2015; Hamilakis and Duke 2007; González-Ruibal et al. 2018; Smith 2004). Such critics argue, inter alia, that privatization programs undermine the rights of local communities and indigenous peoples to control their own heritage. Instead, governments have appropriated national patrimony to serve a global tourism-driven market that generates jobs and profit in the private sector, or to privilege "authorized" narratives about history and culture, often colonialist or class- or race-biased, over the complex, multivocal reality of history in most parts of the world. From this critical perspective, engagement with the forces of capitalism in any fashion may contribute to the

subjugation of disempowered people, reinforcement of a repressive political system, and the debasement of archaeology.

International Perspectives

A limited number of scholars have conducted research touching on aspects of the private sector role in heritage management (Aitchison et al. 2014; Messenger and Smith 2010; Wheaton 2008; Smithuijsen 1998). What emerges from these studies is a picture of policies, values, and instruments that vary widely across the world and feature mosaics of international, national, regional, and local rules that often are inconsistent or uncoordinated. To survey a topic of this complexity, one digestible approach is to consider practices on a sectoral basis: archaeological practice, museum and heritage site practice, and built heritage conservation.

Archaeological Practice

The degree of privatization in archaeological practice is highly diverse. The United States and the United Kingdom, the two countries most deeply committed to privatized archaeological enterprise, have the most comprehensive data on the sector. The commercial CHM market approaches $1 billion annually in North America and €1 billion in Europe, conducts 80–90% of all excavation work, and dwarfs the funds allocated to the academic field research each year (Aitchison 2015; Ferris and Welch 2015, 74). Most of that funding comes either from private contractors, under the "polluter pays" model for private construction activities, or from government agencies complying with national heritage protection legislation. Of the estimated 6120 anthropologists and archaeologists at work in the United States in 2017, three-fifths work in the private sector positions including CHM and engineering companies, while 31% work in government roles, 7% in academia, and 2% in recreational roles (USBLS 2018). The structure is similar in Britain, where again three-fifths work for commercial organizations (Aitchison and Rocks-Macqueen 2013). Often, the United States and the United Kingdom consulting firms also deliver CHM work required in internationally funded development projects in emerging countries, funding for which may come from either private developers or governments.

At another extreme sits Denmark. There, all archaeological research is conducted under the aegis of the national government through authority delegated to the national museum, 31 regional museums, and the 2 Danish universities (Anderson et al. 2014). Developers are obliged to pay for archaeological excavations necessitated by their construction work, but the work is performed only by museum archaeologists. There were about 450 archaeologists working in all fields in Denmark in early 2014, and most were employed by the museums authorized to conduct excavations in the country. Other countries sit on a continuum of privatization and commercialization between these extremes. Surveys to date of global CHM practices suggest that commercial involvement in the CHM process, with inevitable national nuances, is evident in Australia, Brazil, Canada, Ireland, Japan, South Africa, Spain, and Portugal. On the other hand, France, Argentina, Mexico, Panama, Poland, Russia, Thailand, and the Scandinavian countries have more government centric systems, although some private CHM work occurs in those countries. China maintains strict control over heritage management but has devolved most responsibility for CHM activities to provincial and local governments. India also retains central control over archaeological practice but has encouraged involvement by NGOs in public-private partnerships to preserve its heritage.

Museum and Historical Site Practice

While comprehensive global studies remain to be conducted, private sector actors are imbricated throughout the museum and historical site sector in ways that defy generalization. Virtually every country in the world has placed some national parks and seminal historical structures under some form of public ownership. National, regional, and local listing of historical buildings,

which are then subject to protective regulation, is commonplace globally. Museums displaying the archaeological and historical patrimony of countries are typically under national government control, even in the United States, but landscapes, museums, and historic properties often are owned privately.

The United States has perhaps the least "nationalized" heritage sector. There are more than 33,000 museums and related organizations in the United States (IMLS 2018), yet the Smithsonian Institution museums are the only ones to receive routine Federal government financial support, which totals less than $200 million annually. The National Park Service owns and manages 417 properties, about half of which are historical sites, with an additional 49 National Heritage Areas that are public-private partnerships of state, local, and private sector entities that manage historical landscapes and buildings (NPS n.d.). Most of the remaining museums and sites in the United States tend to rely on nonprofit organizations to finance and manage their operations, even though some act as agents for local or State governments who are the legal owners. Altogether, museums and heritage sites generate over $15 billion in annual revenue in the United States (BOC 2018), but the best estimates are that only between 15% and 25% of those revenues are provided by governments.

The most comprehensive study of the UK museum sector (Larkin 2018), still in progress, has identified around 2500 museums, including some archaeological sites, in 2017 (J. Larkin, Pers. Comm, 3 July 2018). The largest national museums in the United Kingdom operate as non-departmental public bodies (NDPBs) that are subject to oversight by a government department that provides their core funding, although they also are mandated to raise funds from commercial and philanthropic sources. In a significant experiment, the agency formerly known as English Heritage, which owns 400 of the United Kingdom's most important monuments, including Stonehenge, other archaeological sites, and some "stately homes," was restructured in 2014 into a trust structure and directed to transition by 2023 from government funding to private financing. UK national and regional governments provide some financial support to other museums and heritage sites, but the vast majority of museums opened in the 1960–1990 period were independent organizations that received no state support. The leading source of financing for projects that fall outside conventional government support is Britain's Heritage Lottery Fund (HLF), a unique NDPB that distributes about one quarter of the net proceeds of Britain's national lottery to local governments, non-governmental museums, and community groups to fund heritage-related projects.

Italy has a constellation of more than 4500 archaeological sites, monuments, and museums (Dicorato n.d.), about one third of which are privately owned, usually by nonprofit foundations. The remainder are managed by municipal governments, except for about 400 museums and sites under national government control. At least until the banking crisis after 2007, many of those projects were funded by foundations associated with Italy's banks, which are required to dedicate a portion of their profits to philanthropic undertakings. Austerity policies following the Great Recession sharply reduced funding for heritage in Italy and have encouraged experiments such as devolution of financial and operational management to local sites, as briefly occurred at Pompeii; encouragement of private foundations to fund conservation, as at Herculaneum; encouragement of national museums to seek outside funding; and acceptance of private funding to restore iconic structures, such as a controversial project at the Colosseum. A generous new tax incentive to encourage private support of heritage was made permanent in 2017.

Hybrids of devolved public and private finance, ownership, and management of museums and heritage sites are evident in other countries. The Netherlands is well known for its policy of "autonomization" of its national museums. In Mexico, where the central government has a near monopoly over cultural heritage, community-owned museums that rely on outside funding to present local cultural and historical material emerged in Oaxaca and spread elsewhere in the country (Robles García and Corbett 2010). On the other hand, China's museum structure is

devolved to local governments (Zan 2014), an approach that is perhaps necessary in a country with several hundred thousand sites and museums and limited enthusiasm for a privatized heritage management sector.

Built Heritage Conservation

Built heritage is threatened by rapid urbanization, which increases demand for up-to-date commercial and residential structures, but nurtured by a tourism industry that depends on preserving the aesthetic, historical, and romantic appeal of old buildings. Public-private partnerships with developers have become the go-to standard for reviving urban cores and historical building throughout the United States, Europe, and much of the Western world (Macdonald and Cheong 2014).

Government-managed lists of historical buildings and critical urban areas, which are common globally, define the agenda and regulatory context for potential partnerships, but the structure of those partnerships varies dramatically. Private parties may merely provide building maintenance and management services for a fee, or they may offer financing to government agencies, or they may assume complete responsibility to invest in the conservation, reuse, ongoing maintenance, and management of structures in return for a profitable revenue stream. Governments may offer regulatory relief, cash or tax subsidies, or direct support such as building road and utility infrastructure required for property development. Government practice varies among countries, but not as dramatically as in other areas of heritage management. In most of the world, residential and commercial properties are privately owned and operated, even when subject to protective listing and regulation. As a result, private sector resources, given the right incentives and disincentives, may be mobilized. Regulatory regimes, and the degree to which they are enforced, do vary widely, but private sector involvement in built heritage preservation is nearly universal.

NGOs also collaborate extensively with local governments, businesses, and communities to preserve heritage sites. They do so through grants, training, and direct intervention. For example, The Aga Khan Trust for Culture (AKTC) has played a leading role in revitalizing urban centers in the Islamic world and in preserving and presenting tangible and intangible Islamic culture. AKTC projects are conducted in conjunction with national and local governments and local community institutions. The Indian National Trust for Art and Cultural Heritage and smaller NGOs work on similar projects on the Indian subcontinent. The World Monuments Fund partners with governments, private companies, and local communities to preserve threatened historical landmarks and cultural sites throughout the world. Other NGOs, such as the Global Heritage Fund or the Sustainable Preservation Initiative, work with governments, NGOs, and community groups on heritage conservation projects worldwide. International governmental organizations (IGOs), including the United Nations-related agencies or the affiliates of the World Bank, collaborate directly with governments and others to provide financing, technical advice, substantive expertise, and training for projects, such as the restoration of urban centers, and deliver targeted training for heritage managers and conservators in emerging economies.

Future Directions

Setting aside policies in China and a few other countries, governments around the world cannot meet the need for heritage management without private assistance. Thus, an initial trend to expect in future government policy is further experimentation. Countries may seek to adopt nonprofit funding models, as is taking place in Italy or with the United Kingdom's restructuring of English Heritage. To do so, legislation to facilitate the formation of nonprofits will need to become commonplace, and tax or other incentives to promote private philanthropy will need to be implemented. There also is growing interest in corporate philanthropy, known as corporate social responsibility (CSR), whereby corporations donate to organizations in regions where they identify governments or communities that are important to their business interests. CSR donations are driven as much by marketing priorities as

by eleemosynary considerations, but CSR has the potential to dramatically increase resources for heritage management. However, CSR and individual philanthropy can only thrive if the public and governments accept the legitimacy of private charitable giving. Vilification of private donors, as has occurred in Italy in recent years around the privately financed conservation of public buildings, is counterproductive.

Quasi-governmental financing also may come into play. The UK's Heritage Lottery Fund, a backbone of support for culture and heritage in Britain, is a model for utilizing revenues derived from human foibles for public good. Critics may argue that government lotteries both encourage behaviors that are damaging to individuals and families and constitute a form of revenue generation that is highly regressive, drawing proportionately more from individuals in lower-income categories. Furthermore, recent declines in lottery sales forced a contraction in HLF spending, a reminder that even gambling is affected by economic conditions. Nonetheless, other countries have contemplated creating HLF-like structures, and perhaps more will do so.

Crowdfunding of heritage projects has been viewed as a potential way to tap the resources of passionate members of the public. Experience to date (Bonacchi et al. 2015), however, suggests that resources available from crowdfunding are both limited in amount and highly dependent on the ability of organizations to create a sustainable and engaged community of donors. Crowdfunding experiments using general-purpose Internet platforms have not been successful, and with rare exceptions, even specialized sites focused on heritage management have been unable to raise funds consistently. While crowdfunding may be a vehicle for the future, it is unlikely for some time to be more than a niche source of funding.

A problematic trend in financing for culture generally is the increasing interest in the social impact of both government and philanthropic spending. To some degree, the impact movement reflects a merger of neoliberal concern for efficiency with a philosophical school, known as effective altruism, which insists money should be spent where it will do the most social good. When this view is harnessed to government agencies that seek to ensure they get the most value for the taxpayer dollar, the result is new demands by governments and private philanthropists for concrete evidence that spending is having clear impact on individual lives or the economy in general and that programs in place are the most cost-effective vehicles to achieve those effects. This approach is widespread in the United States and in Europe in social welfare, health care, and other social program areas and is making its appearance in cultural heritage. The EU, for example, has funded a study entitled Cultural Heritage Counts for Europe (CHCfE 2015), which attempts to make the impact case for heritage management. If positive impacts can be demonstrated to reduce government costs, for example, by improving educational outcomes, proponents of impact-based philanthropy also suggest that projects delivering those results may be financed through "impact bonds" that would yield higher returns to investors if desired impacts are demonstrated in practice. However, universally accepted metrics for the impact of heritage management activities and reliable data demonstrating those impacts are not yet available.

Processual Archaeology and Art Studies

Mara Basile
Instituto de las Culturas (IDECU), Universidad de Buenos Aires (UBA), Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET), Buenos Aires, Argentina

Introduction and Definition

As a reaction to traditional normative approaches and as a product of a specific sociopolitical context – the heyday of modernity (Criado 2012) – processual archeology posited itself as the necessary change toward more rigorous and sophisticated analytical methods. This epistemological reorientation entailed drastic changes. The normative definition of culture, perhaps systematized by the processual archaeologists themselves (Lyman and O'Brien 2004), was substituted by a functional definition treating cultures (i) as vast information systems, made up of several functionally integrated subsystems, and (ii) as an extrasomatic means of adaptation to the environment. Therefore, culture involved practice and had adaptive functions to deal with the restrictions of their ecological contexts (see the entry on "▶ Archaeology of Art: Theoretical Frameworks" in this encyclopedia).

In this new scenario, the focus of archaeological research was the cultural process and the explanation of the identified regularities in the cultural systems (Binford 1965, 1983). Changes in the aspects of cultural systems were interpreted as adaptive responses to alterations occurring in the environment or in adjacent and competing cultural systems. Hence, human innovation and inventiveness were excluded as forces capable of triggering change, a change that used to be explained as a result of external factors (Trigger 1992).

These profound conceptual changes are derived from a set of methodological innovations, many of which currently continue to define the archaeological research: (i) the systemic conception of culture and the recognition that cultural systems always operate at a regional level implied the development of regional research strategy in field investigations taking into account not only the system components but also surrounding environmental and social milieu; (ii) the introduction of quantitative analysis in order to identify regularities in archaeological record and, as a result, to infer similarities and differences among cultural systems; (iii) the recognition of the relevance of probability sampling and (iv) the multidisciplinary efforts; and (v) the application of hypothetico-deductive epistemology.

Although the analysis of visual manifestations was not a main concern, the conceptual and methodological changes carried forward by processualists are derived in a particular way to look at the material culture and therefore had great influence on art studies. Positioned from a critical perspective to previous normative studies, the processual approaches to art are very tied to style concept which involves diverse aspects of image making and display (see the entry on "▶ Style: Its Role in the Archaeology of Art" in this encyclopedia). Archaeologists following this perspective begin to relate the different artistic manifestations with the societies that produced them using more refined analytical techniques. There is an interest in the quantification and the demonstration or

refutation of specific hypotheses, and the adaptive and functional aspect of art as a cohesive element of human groups and as the material correlate of their ethnic identities is highlighted.

Their new objective (to explain the cultural process) led to emphasize the primacy of objects, conceived as cultural products in the sense of being adaptive component of the cultural system in operation and pattern recognition (Conkey 1990). Therefore, the analysis of the variety of forms, designs, compositions, and techniques deployed over fix or portable mediums has been interpreted as a key evidence through which it identifies group identities, constructs models of social organization, measures levels of social interaction, and defines alliances, networks, and information channels between them. Although there were qualitative and quantitative analyses over rock art (Jochim 1983; Keyser 1977; Schaafsma 1985), engraved bones, and lithic figurines (Gamble 1982; White 1992), the main focus was the definition and comparison of variation in portable art, particularly in the study of decorative and morphological variation in pottery (Deetz 1965; Hill 1970; Conkey 1980; Sackett 1977, among others).

Academic involvement in rock art research, at least in North America, has been sporadic, infrequent, or marginal (Francis 2005) as a result of processual insistence on the study of ecological adaptations at the expense of historically specific artistic traditions (Trigger 1992) and due to the difficulty in reliably dating the images (Klassen 2005). In South America, there has been prolific and solid academic analytical tradition of rock art study which generated specific conceptual perspectives oriented to local problems that either anticipate or adapt in novel ways, elements of theoretical frameworks developed in academically hegemonic countries (Fiore and Hernández Llosas 2007; Troncoso et al. 2017). Then, although rock art research remained peripheral to mainstream archaeology, the emphasis on quantification and description reflects the influence of the theoric and methodological premises of this framework to the analyses conducted during this period (Klassen 2005).

Historical Background

Prior to the shift in the research program and the development of the problem oriented and generalizing approach of processual archaeology, the emphasis was placed upon chronologically diagnostic artifacts and their movements through time and space (see the entry on "▶ Processualism in Archaeological Theory" in this encyclopedia).

The new objectives defined by processual archaeologists are derived, specifically, in the field of artistic studies, in the approach of peculiar themes through the implementation of specific methodologies. Although it was not one of its central focus, the analysis of visual manifestations, particularly those deployed on pottery, was considered as a way of interpreting variability in terms of those facets that coincided with its ontological, epistemological, and conceptual positioning (Fiore 2009).

Perhaps what best sums up their research intentions is the tracking and identification of the adaptive functions of visual manifestations. Therefore, initially (in the middle of the 1960s), these studies will put them at the service of defining bounded space and temporary distribution in order to infer or to construct models of social organization and tend to focus on the role visual designs play in contexts of interaction, exchange, establishment of alliances, craft specialization, etc. (Plog 1978).

These data were contextualized by their environmental setting to characterize the natural and social context in which these "adaptive strategies" were operating. These studies tended to see art production and use as a means of overcoming environmental stress and potential competition for resources triggered by environmental changes and/or demographic pressure by creating and reinforcing social bonds.

Some of the first art studies derived from the processual framework resulted in the use of ceramic design analyses to infer residence models of prehistoric communities and to measure levels of social interaction (Plog 1990). It was supposed that, if women produced the ceramic vessels for their families and being this knowledge transmitted from mothers to daughters, design

characteristics should tend to be homogeneous in matrilocal communities and random in the patrilocal ones (Deetz 1965). These approaches excluded the possibility that some of the ceramic styles documented could be not locally manufactured and the result of, for example, interregional exchange (Trigger 1992).

As time goes by, it began to be recognized that pattern tracing had to be sought at multiple levels, and thus the explanations of its causes became more complex and richer, giving rise to the belief that certain types of attributes differ in different ways than others and thus may be affected by different factors (Conkey 1990). In this context, specific functions began to be assigned to the different elements that define the visual manifestations that started to be conceived as a means of communicating, transmitting, and exchanging cultural information and establishing and maintaining social boundaries (Wobst 1977; Plog 1980; Flannery 1976). Thus, motifs, compositions, and forms displayed in diverse media were considered as ethnic, social, and territorial markers, as a means of differentiation of status or gender operating in specific contexts (Conkey 1990; Sackett 1977).

A different approach was developed by Dunnell (1978) who considers that although there are explainable behaviors in evolutionary terms through mechanisms such as natural selection, there are others that must be explained in terms of stochastic processes because they are adaptive and neutral. In this context, he sustained that "many specific trait forms may lack adaptive value, but a reservoir of variability, some of which may ultimately acquire adaptive value with changing conditions" (Dunnell 1978: 199). In this context styles, including image making and display within them, will continue to be useful tools for chronology, and defining spatial interaction meanwhile will be the functional elements which can be explained with evolutionary processes.

Within the line that tends to assign specific functions to visual manifestations (or artworks) are included the works of Sackett (1977, among others) who considers that the style that acquires the archaeological record of each society results from the choices taken within a broad range of equally valid alternatives. Those elections will be specific to a social group at a particular time and will be socially transmitted. However, they are continually reviewed from changes in social interaction with other groups and by permanent exposure to alternative isochrestic options. This variety, resulting from the series of decisions equivalent in terms of use taken by the artisan, is defined by tradition and therefore has diagnostic value in the archaeological identification of cultural traditions and is directly related to the amount of social interaction between individuals, groups, or villages. This type of approach assumes that ceramic morphology is determined by utilitarian functions, while decoration adds additional nonfunctional variation through which certain kind of social information is expressed (Sackett 1977). Consequently, each group will possess its own style, and the degree of stylistic similarity represented in the material culture of two groups can be understood as a direct expression of their ethnic relationship. Sackett argues that the iconic properties of style constitute the ethnic message generated by the conscious, deliberate, and premeditated behavior of artisans, with the intention of identifying and maintaining boundaries between social groups. "Any class of objects is dualistic in nature, and whether it assumes its functional or stylistic mode depends on the context in which it is viewed" (Sackett 1990: 41).

Within this same spectrum but moving away from the idea of image making as a by-product or passive reflection of culture systems or individual motor habits (Plog 1983) are inserted the works that emphasize the importance of the stylistic variation in the exchange of nonverbal information with functional and adaptive content (Wobst 1977). Thus, stylistic variation may be used in certain contexts to communicate information about the identity of the maker or user, about his social group membership, status, wealth, religious beliefs, and political ideology. Then, by assigning to visual manifestations the concrete adaptive function of constituting means through which messages could be encoded in the absence of receivers and then decoded in the absence of emitters, the style/function opposition is

challenged. However, Wobst (1977) suggests that these kinds of messages tend to be less effective with increasing social distance between the sender and receiver. Thus, the variation of visual manifestations would be expected to be used in information exchange only under specific social conditions (Plog 1983). From this point of view, the study of visual manifestations can provide us with information about human groups and their interactions and relations between individual and society (Berrocal 2005). Although the concept of residual and nonfunctional style was replaced, adaptive thinking persisted.

In the bounds of this same framework, Schiffer (1972) developed its flow model that had a crucial effect to archaeological interpretation of the archaeological record in general and had concrete applications in art studies. His proposal is aimed at explaining the various processes of procurement, manufacture, use, maintenance, and discard in which artifacts take part, entering the archaeological record at many points through this life history. In this line, he highlighted the need to understand the natural and cultural processes that create and transform the archaeological record before the archaeologists analyze it for reconstructing past human behavior. In tune with this proposal, theoretical models were elaborated anchored in the development and study of the operational chain to produce portable art and the resulting pattering, explicitly the Aurignacian material representation (White 1992) and rock art (Aschero 1988). These proposals far exceed the objectives of the processual framework allowing to approach these materials from diverse theoretical perspectives (see the entry on "▶ Archaeology of Art: Theoretical Frameworks" in this encyclopedia). Specifically in the case of the model generated to analyze rock art's sequence of production, it involves the development of conceptual tools to approach the types of residue left by each stage in the archaeological context including concepts related to the context of signification, conformed by the functional context of execution and the thematic context of representation (Aschero 1988). His proposal made it possible to expand the focus from art's ideological elements to the technological ones (see the entry on "▶ Archaeology of Art: Theoretical Frameworks" in this encyclopedia) and was exceptional for the way in which rock art was approached in South America (Fiore and Hernández Llosas 2007).

Key Issues/Current Debates

As every theoretical framework, processual archaeology, its objectives and main focus, should be analyzed in the specific historical-academic contexts in which it was developed, taking into account the other frameworks with which it was dialoguing and discussing and from which it was trying to differentiate. Within this line, it is interesting to note that, despite the rupture sustained with traditional archeology, at least in the field of artistic studies, certain aspects of normativism prevailed (Conkey 1990). Some authors have even suggested that many of the normative propositions were crystallized when they were explicitly used in the interpretations of the data generated by the processual archaeologists who analyze ceramic designs and tend to explain their similarities using arguments analogous to the basic assumptions which archaeologists always have used in defining culture areas (Lyman and O'Brien 2004; Flannery 1976).

Within the processual framework, material record was conceived as coded information about variability and the functioning of past cultural systems to be read by archeologists. Pattern recognition was a priority, and visual expressions were initially a residual kind of formal variation that the latter was conceived to be a functional component of cultural system analyzed (Conkey 1990). Then, although there is much diversity in these approaches and there have been changes in them over time, the core of their main proposals was severely challenged because of (i) its *ecological determinism*; (ii) its *conception of culture as a means of adaptation*, which leaves aside "non-adaptive" uses of art; (iii) its *instrumental view* of visual expressions as fulfilling a function for a culture conceived as a homeostatic system which paid little attention to its internal contradictions; (iv) its *search for regularities* tending to ignore the contextual particularities; and (v) its use of

inexplicit, intuitive criteria for isolating the analytical units, lack of replicability, or equivalency (Plog 1978; Hodder 1990; Weissner 1990; Pauketat 2001, among others).

Although the complex causes of variation in the design of visual expressions demand to contemplate different materials and types of artifacts, processual approaches, in spite of the exceptional analysis of other mobile and fixed media, tended to focus the analysis on the variety registered in ceramic vessels (Plog 1983). Within this framework, the design similarities tend to be still explained in terms of cultural traditions that result from the passive expression of group or individual identity (Weissner 1990), assuming that these decorative regularities, in the morphological, decorative, and technical aspects, exist because they fulfill a specific function: the communication of that identity (Jones 1997). Even if the normative ontology of the traditional approaches to art was challenged by the ecological and functionalist ontology generated by the influence of processualism, it was not fully replaced (Fiore 2006). At some point, the main, and not least important, divergence from normativists lies in the diversification of social sources capable of producing those patterns, but they retain their function as a monitor of the degree of cultural affinity between social groups (Berrocal 2005). In this way, "the complexity of the relationship between stylistic variation and social, religious, economic, and demographic factors has often been overly simplistic" (Plog 1978: 128), and the capacity of art tended to be reduced to the social functions of transmission of information related to membership (Hodder 1990).

New archeology's insistence on the recognition of regularities meant that the concrete contexts in which variation took place, the way artworks had been used and participated in the production of meaning, were ignored (Pauketat 2001). It is interesting to note that this priority of pattern recognition to be explained in terms of ecological determinism constrained the study of the diversity of causes and factors that model human actions. Visual expressions, its uses, its similarities, and changes should be contextually analyzed and are often the result of multiple factors that cannot be reduced exclusively to the ecological ones (Trigger 1992). The new archeology that "began to speak of societies, social processes, systems and adaptations did not say much about man, woman and the human" (Criado 2012: 41).

However, just as normative archeology was a logical prelude to the systematic study of culture from the processual and functional perspective proposed by new archaeologists (Trigger 1992), the conceptual and methodological development elaborated within this framework was fundamental to anchor the new questions, the criticisms, and the later syntheses. In fact, these critics derived in the hermeneutic turn that defined the post-processual archaeology and in the theoretical turn to study the symbolic dimension of reality, within the same processual framework, the so-called cognitive archaeology (Criado 2012).

International Perspectives and Future Directions

There is a general agreement with respect to which processual archeology represented a reorientation of our perception of the material record in methodological and technical domain more than in theoretical ones (see the entry on "▶ Processualism in Archaeological Theory" in this encyclopedia). Beyond the sharp criticisms and questions to which their interpretations have been subjected, the core methodological procedures introduced by processual archeology are still at the basis of any archaeological research program:

i. The search for regularities without losing views of the particularities continues to be central for archeological investigation.
ii. The efforts to explicitly define the analytical categories (i.e., type of motifs, size, color, spatial composition, and techniques, among others) and the methodological strategies employed in order to allow its replicability.
iii. The use of quantitative methods for the initial and exploratory ordering of the recorded variability.

iv. The inter-site, interregional, and intermedia comparisons are still useful initial steps to locate similar visual designs relatively in time, location that should be complemented and corrected through direct dating.

As Criado (2012) proposes, it is time to reconcile the theoretical currents that constitute the basis of the archaeological tradition, a tradition oriented roughly to the definition of forms, functions, or meanings of material records. These views do not have to be necessary incompatible since the incompatibility lies specifically in the conditions of production and reproduction of knowledge and academic life. It is possible to construct an integrative perspective that accounts for the archaeological record and visual manifestations as form, function, sense, and entity to be managed (Criado 2012). Maybe today it is not about thinking in terms of surpassed phases but in terms of internally consistent approaches that allow crossings and combinations between diverse inquiries and interpretations with rigorous methodologies which allow us to account for the complexity of the practices behind the production of the objects, designs, images, and colors that circulated being part of the multiple domains of the life of our ancestors.

Processualism in Archaeological Theory

Steven A. LeBlanc[1] and Patty Jo Watson[2]
[1]Peabody Museum of Archaeology and Ethnology, Harvard University, Cambridge, MA, USA
[2]Department of Anthropology, Washington University, St. Louis, MO, USA

Introduction

For approximately 20 years during the 1960s to the 1980s, lively discussion about theoretical and methodological issues characterized Euro-american archaeology. Much of the debate centered upon an approach called New Archaeology or processual archaeology that originated in the United States. In this entry we provide our perspectives upon the mid-twentieth-century controversies about the nature and goals of archaeology and make reference to some of the more prominent subsequent developments.

Definition

We use the phrases "New Archaeology" or "processual archaeology" to mean a problem-oriented, generalizing rather than a particularizing approach toward archaeological data, with the goal of advancing knowledge about social, cultural, and political processes characterizing past human societies. This view derives from the development of anthropology within the United States during the first few decades of the twentieth century as a holistic study of humankind from origins to the present day. Anthropology was

conceived as a social science wherein archaeologists, ethnographers, linguists, and physical anthropologists carried out worldwide comparative cross-cultural research on humankind, past and present, wherever relevant evidence could be found.

Historical Background

Prior to the rise of processual archaeology, however, Americanist archaeologists of the early to mid-twentieth century focused quite narrowly upon chronology and comparative typology. There was such a heavy emphasis upon chronologically diagnostic artifacts and their travels through time and space that the phrase "time-space systematics" was and still is often used to describe 1930s–1950s Americanist archaeology. Although efforts were made during this period by a few archaeologists to broaden the scope of archaeology in the USA, these had no discernible effect. Neither did a closely reasoned, strongly argued, book-length critique that appeared shortly after World War II (Taylor 1948; see Maca et al. 2010). During the early 1960s, however, Lewis Binford began to attract considerable attention to his views concerning anthropological archaeology. Binford's program for change (Binford 1962, 1964, 1965) was labeled "processual archaeology" by many of its advocates (e.g., Flannery 1973) and instigated considerable methodological and theoretical ferment. In his initial manifesto, Binford (1962) begins by quoting the well-known statement of Gordon Willey and Phillip Phillips that "American archaeology is anthropology or it is nothing." He then proceeds to assess the performance of Americanist archaeology with respect to supporting the aims of anthropology as the integrated discipline it was supposed to be. He defines those aims as explicating and explaining "the total range of physical and cultural similarities and differences characteristic of the entire spatial-temporal span of man's existence," notes that while major contributions have been made by archaeologists to explication of past cultural systems, they have done virtually nothing about explanation of those past cultures as functioning systems. Binford's definition of explanation is:

> . . .simply the *demonstration* of a constant articulation of variables within a system and the measurement of the concomitant variability among the variables within the system. Processual change in one variable can then be shown to relate in a predictable and quantifiable way to changes in other variables, the latter changing in turn relative to changes in the structure of the system as a whole. This approach to explanation presupposes concern with process, or the operation and structural modification of systems. (Binford 1962: 217, italics in original text)

He goes on to declare with Leslie White that culture is "the extrasomatic means of adaptation for the human organism" to the total physical and social environment (Binford 1962: 218) and that the "formal structure of artifact assemblages together with the between element contextual relations should and do present a systematic and understandable picture of *the total extinct* cultural system" (Binford 1962: 219, italics in original text). Binford notes that all cultural systems are made up of three subclasses of material culture. These are the technomic, which have "their primary functional context in coping directly with the physical environment"; the socio-technic, which are "the material elements having their primary functional context in the social subsystems of the total cultural system"; and the ideo-technic, which have "their primary functional context in the ideological component of the social system" (Binford 1962: 219).

Binford's subsequent research and publications, however, as distinct from this initial programmatic essay, centered so heavily upon the technomic aspects of past cultures that one of his peers aptly characterized Binfordian processual archaeology as "econothink" (Hall 1977). There were also significant differences in emphasis among processualists about the ultimate goals of their endeavor (Flannery 1973; Watson et al. 1984), but there was general agreement upon the importance of explicitly problem-oriented, hypothesis-testing research designed to secure knowledge of the human past that would advance the goals of archaeology conceived as social science.

Thus, the original debate centered upon archaeology as a very narrow kind of history vs. archaeology as (social) science, but more was at issue than just the difference between particularistic and generalizing goals. It was thought that prehistorians concentrating upon time-space systematics attempted to document the archaeological facts accurately but that they explained those facts by appeals to common knowledge. That is, they relied upon explanations that were untested, and therefore not scientific. A classic example is the issue of migration. Obviously, there have been many migrations in the past, a proposition no reasonable person would deny. To invoke migration as an *explanation* for cultural change, however, is problematic. What is the evidence that there actually was a migration? That is, how does an archaeologist establish that a migration happened at the time and place in question? Even if there is convincing evidence for such a migration, what further evidence indicates that this migration caused the change under investigation rather than some alternative or additional causal event or process? *Why* was there a migration? Binford and other advocates of the processual approach insisted that archaeologists could and should do much more than simply documenting cultural change in the archaeological record, saying a migration caused it, and leaving it at that. Peter Bellwood (2009) provides a good recent example of the alternative approach advocated by Binford as he attempts to understand why farmers migrated successfully under some circumstances but not others.

Another objection to archaeology practiced as narrowly focused cultural history was that the cultural historians were content simply to describe past objects and events with little or no attempt to understand the configurations they were describing. Trait listing and time-space systematics seemed to be the primary goals of archaeological endeavor. Hence, the main point the processualists were making was not that cultural history is bad per se but rather that it differs significantly from the broader approach they proposed and that it has far less scientific value.

The cultural history vs. cultural process debate – as it took shape in the 1970s – seems to be over. Most archaeologists understood the differences just described, and many broadened their approaches to include explicit problem definition prior to fieldwork as well as formulation of testable hypotheses concerning the expected results of that fieldwork. Even those who continued to be particularistic cultural historians became more careful about the basis for their interpretations of the past.

Processual archaeology was eagerly embraced by most younger Americanist practitioners. By the late 1970s, processual archaeology was so widely accepted in the USA that NSF peer review panels for archaeological proposals, for example, required clearly defined and justified anthropologically significant research problems with clearly defined research designs specifying expectations (hypotheses) to be tested by the proposed fieldwork. One 1970s observer – Robert C. Dunnell – did voice some serious qualms, however:

> The rapid development of CRM has to a certain degree upset the normal progress of disciplinary development (in Americanist archaeology) because it threatens to make permanent the condition of the discipline at a time in which rigidity is least warranted. (Dunnell 1979: 449)

As he makes clear, Dunnell's reservations derived in large part from his concern about the impact of Cultural Resource Management in the USA subsequent to the 1974 addition (via what was known at the time as the Moss-Bennett Bill or the Archeological Data Preservation Act) of archaeological remains to federal environmental impact legislation. Fortunately, Dunnell's worst fears did not come to pass, thanks to strenuous and unremitting efforts by both academically based and CRM archaeologists working with each other and with American Indian groups as well as other local communities and stakeholders. Such efforts continue to the present time and have caused significant alterations in the scope and practice of archaeology in the USA, the great majority of which is now CRM archaeology.

While CRM legislation was transforming the organization of archaeology in the USA, however, a different set of powerful challenges to the

theoretical core of processualist Americanist archaeology arose in England and Western Europe (Hodder 1982; Shennan 1986). In one of the first formal accounts of major disagreement with the processualist agenda, Ian Hodder (1985) used the term "postprocessualism," which is still a convenient label for the wide array of anti-processualist as well as non-processualist perspectives that emerged within Euroamerican archaeological discourse during the 1980s and after.

As noted above, in Binford's first call to reform Americanist archaeology (1962), he refers to potential recovery from the archaeological record not only of technomic but also socio-technic and ideo-technic data enabling inferences about ancient sociocultural and cognitive systems. Many early processualist studies were well conceived and well executed, and several made careful use of ethnographic data (e.g., see Hill 1970). Moreover, some archaeologists undertook archaeologically relevant ethnographic fieldwork themselves in aid of specific archaeological projects (Binford 1978, and see David and Kramer 2001). The great majority of research by processualists, however (especially that of Binford, the primary role model), centered upon relations among the subsistence-settlement systems of ancient communities and their ecological contexts.

Hence, although many 1960s–1970s processualist efforts were very successful, they were also quite narrowly focused, leaving the practitioners vulnerable to critiques by post-processualists who pointed out the general lack of attention by processualists not only to what Binford had called socio-technic and ideo-technic realms of culture and society but also to the socio-political contexts of archaeology as a disciplinary community and of individual archaeologists operating within contemporary nation-states. By the mid-1980s, one European archaeologist confidently stated that the center of gravity for theoretical archaeology had shifted from the USA to Europe and that "the days when keen young undergraduates and research students eagerly awaited the next issue of *American Antiquity* are long gone" (Shennan 1986: 327).

Key Issues/Current Debates

As outlined above, key issues for processualist archaeologists initially were definition of significant, anthropologically relevant research goals and the best means for reaching them via scientific methods. In fact, however, most early processualist studies were focused upon investigating past physical and biological environments of archaeological sites and regions with emphasis upon subsistence regimes and settlement systems characterizing communities that once inhabited those ancient environments. Early advocates of New Archaeology or processual archaeology were more intent upon scientific method than upon social theory, more upon epistemology than ontology. Methodological reform of traditional time-space systematics archaeology was certainly warranted, but just as that reform became widely accepted, the narrowness of the original processualist program was vigorously attacked by archaeologists in England and continental Europe who were not committed to archaeology as anthropology or archaeology as science vis-a-vis archaeology as traditional cultural history or art history. They were also conversant with large bodies of literature on social theory that were not then present in the scholarly backgrounds of most Americanist archaeologists.

The initial postprocessualist impact during the 1980s and 1990s was the entering wedge for an enormously broadened scope of archaeological debate well beyond that defined during the 1960s–1970s by processualist archaeologists. A vastly wider array of orientations and goals was strongly advocated, ranging from symbolic-structuralism and other paleo-cognitive orientations to latter-day Marxian and post-colonialist perspectives. There was considerable emphasis upon issues of gender, both past (i.e., seeking evidence of gender-based activities in the archaeological record) and present (e.g., recognizing gender-based differences in contemporary beliefs about appropriate education for male vs. female student archaeologists). Much concern was also directed toward descendant communities and indigenous groups, to contemporary processes of

domination and resistance in colonial situations or totalitarian nation-states, and to the political uses of archaeology. Postprocessualists urged archaeologists to practice their profession as self-aware and socially responsible citizens of the modern world.

International Perspectives

Processual archaeology was a mid-twentieth-century development, created and initially promulgated by anthropological archaeologists in the United States. The wide array of orientations and approaches loosely grouped under the rubrics of postprocessual (and by now *post*-postprocessual) archaeology is primarily a product of European archaeologists drawing upon European social theory and philosophical systems. The original global forum for archaeological research, the International Union of Pre- and Protohistoric Sciences, was founded in 1931. The heavily Eurocentric IUPPS was a scholarly organization overtly disengaged from nationalist and global political venues. In 1986, the IUPPS was challenged by a new international organization: World Archaeological Congress (Ucko 1987; Gero 2008). Although the two were originally hostile, even antithetical, at present they are more or less complementary. Whereas the IUPPS maintains much of its original scholarly character, WAC is not only global and cosmopolitan but is also socially responsible, activist, and engaged. The WAC membership is dedicated to what is sometimes called value-committed archaeology, which Gero (2008) says is the archaeology of the future.

Future Directions

New technologies now accessible to archaeologists offer great promise for learning about the past. Perhaps the most spectacular of these is being use of ancient DNA to track specific prehistoric human populations (e.g., the peopling of Asia and Australia, Rasmussen et al. 2011) and interbreeding, or lack thereof, between Neanderthals and archaic *Homo sapiens* (Currat and Excoffier 2011), as well as the histories of domesticated plants and animals (e.g., Marshall and Hildebrand 2002; Zeder et al. 2006). Another fruitful trajectory is the application of techniques long in use, such as obsidian sourcing, to provide empirical means of delineating evidence for ethnogenesis in the archaeological record (Scheiber and Finley 2011: 376–77). Yet another very promising development builds upon the original central concern of processualist archaeologists: interaction between past human communities and their environments. Archaeological data from several locales in the Americas and elsewhere on long-term patterns in human/environment relations are now sufficiently detailed to provide important information that can and should be used to influence national and international policy makers (Fisher et al. 2009; Miller et al. 2011).

For the foreseeable future, WAC will continue to be a global forum for activism by archaeologists everywhere. Such a forum is especially important considering the hard fact – and the commitment necessary to do everything possible to mitigate that fact – of rapid catastrophic destruction of the archaeological record by development of all kinds throughout the world. This includes continuously expanding urbanization; continuously expanding agricultural systems; continuously expanding transportation networks; and increasingly intensive exploration for and exploitation of oil, gas, and coalfields. Concomitantly, there is the equally catastrophic disappearance of once highly diverse traditional lifeways around the globe in the face of increasingly powerful (monolithic, multinational corporate) socioeconomic forces operating everywhere on our planet.

In addition to all the above, myriads of archaeological sites are being and will continue to be damaged or destroyed as will museums, cultural heritage locales, and materials in areas where regional conflict destroys cities, towns, and landscapes. Systematic destruction of the Bamiyan Valley Buddhas is one of the best-known modern examples, but there are a great many more. It appears that both short-term emergency archaeological salvage and long-term restoration of items and institutions pertaining to cultural heritage are permanent necessities in the modern world.

Finally, there will continue to be considerable diversity in the goals of people doing archaeology and, therefore, in the actual practice of archaeology internationally. But the core methodological procedures of processual archaeology are basic to all empirically oriented archaeological endeavors and will remain so far as long as the discipline survives.

Professionalization: Archaeology as an "Expert" Knowledge

Sara Perry
Department of Archaeology, University of York, York, UK

Introduction

Archaeology as a professionalized practice – with accredited specialists, institutional support, defined methodologies, and a coherent knowledge base – has a convoluted history. By some accounts, that history extends back no more than a half century, to the post-World War II era and, in particular, to the 1960s and 1970s. By other accounts, it stretches across multiple centuries (if not millennia), with a range of interested individuals and materials converging at various times and places in the making of archaeological expertise. Typical reviews of such disciplinary development tend to emphasize intellectual progression or the role of a select number of notable people in creating a professional archaeological environment. Iconic publications such as Trigger's (2006) *A History of Archaeological Thought* and Daniel's (1981) *A Short History of Archaeology* bear witness to these tendencies, compiling the rise of different modes of thinking at the hands of a series of heroic-seeming figures (e.g., the United Kingdom-based V. Gordon Childe or the Swedish archaeologist Oscar Montelius) into a cohesive narrative of the discipline's evolution.

Increasingly, however, fine-grained oral historical research and institutional analyses hint at the more or less unquantifiable, broadly informed, and always changing nature of the field. Herein, archaeology's professional culture is shown to be not so easily contained, having long been built up and molded out of methodologies and contributors from different areas of practice. These include both academic and nonacademic specialists engaging with a range of different modes of labor and publicity – from exhibitions to site visits, magazines and public lectures – that go far beyond traditional excavation and artifact studies alone.

The following entry outlines a history of archaeology that acknowledges the variety of experts and forms of expertise that have manifested in professional archaeological work. It builds upon sociological and anthropological scholarship on professionalization and the constitution of expertise (e.g., Carr 2010) and, in so doing, speaks not so much to the conceptualization of the archaeological record, but to the manner by which people and objects have come together to naturalize these acts of conceptualizing.

Definition

While the history of archaeology has been told by many scholars – both historians and

archaeologists themselves – the specific means by which individual interests in old objects were formalized into an internationally recognized speciality legitimated by the university system are less clear. This process of professionalization is typically appreciated as a cumulative and iterative exercise, as people came together through shared concerns and then began to articulate distinctive social and behavioral identities (both spoken and unspoken) linked to specific environments (both formal and informal) that ultimately worked to determine and advance future membership in the group.

Few archaeologists have meaningfully interrogated such exercises in disciplinary formation, but where so, they have tended to draw upon sociological scholarship or social and historical studies of science (e.g., by Pierre Bourdieu, Michel Foucault, Antonio Gramsci, T. Lenoir, J.B. Morrell, Steven Shapin) to define their dimensions (e.g., Moser 1995; Patterson 1999; Smith 2009; Perry 2011). According to this literature, professional culture tends to entail a learned jargon, standard methodologies and conceptual models, recognized spaces of learning (e.g., the field site or laboratory), clear means to disseminate ideas and research results (e.g., publication channels and pedagogical programs), and sustained infrastructure for financing and otherwise supporting these exploits. Smith's (2009) critical reflections on the components of professionalization go further to suggest that student creativity, collegiality, and informal places of knowledge exchange (e.g., tea rooms) are also among those traits crucial to the construction and perpetuation of worlds of expertise.

While the exact "ingredients" for disciplinary success vary by field of practice, as Moser (1995) outlines, the professionalization process – as applied to archaeology in particular – appears to follow a clear trajectory. In the first instance, a body of foundational knowledge is generated by various individuals who come to interact with one another through their common interests. The practice of knowledge creation leads naturally into the demarcation of specific methodologies and terminologies, which then become increasingly refined and embellished through application in the field. Participating in this process thus works to elaborate a particularized cognitive base, increasing its complexity to the point where instructional manuals and formal means of conveying methods, concepts, and interpretations become necessary to sustain development.

So too does it formalize a community of practice around which a sense of expert identity begins to manifest. Participation effectively becomes a rite of passage, socializing individuals and denoting their belonging and inclusion in a now otherwise exclusive group. These individuals are trained by people who are understood to demonstrate competence in the field and that training tends to be oriented towards advancing specific agendas related to such preexisting competencies. But the fluid and social nature of tuition means that, in its very enactment, students begin to generate new networks, procedures, pupils, and associated outputs that further extend the nature of the practice. They then become key to maintaining and furthering the institutional infrastructure required to prop up the many facets of this work. As per Christensen (2011: 9 citing Larson 1977: 17), it is in this moment when "the production of knowledge and the production of producers are united into the same structure" (and that structure is supported by paid labor) that a profession comes into being.

Together, such activities, products, and people constitute what Moser (1995) calls a disciplinary culture – a community subscribing to an interlinked and self-reinforcing set of cognitive and cultural identities. Such a community holds the monopoly over a body of knowledge and methodologies: its members read similar things, participate in similar pursuits, speak a similar language, cite one another's works, and collectively respond to the needs of a wider public. At once, they exclude this wider public via their apparent solidarity and, in so doing, demonstrate the simultaneously "repressive and productive" Foucauldian power dynamics regularly observed in the manifestation of expertise (see Carr 2010: 18).

Indeed, definitions of professionalization often also revolve around amateur/expert status distinctions, where less-knowing dilettantes or hobbyists are seen to be slowly pushed aside by more

informed and "qualified" workers. Such a perspective tends to denigrate or entirely dismiss the contributions of so-called amateurs to the overall institutionalization of archaeology. At the same time, it often separates amateurs out as a self-defined, self-segregating body of individuals who do not make their living via archaeological knowledge making, but who engage in aspects of its practice purely for leisure's sake. It is in these very processes of ostracizing such people from the production of valid knowledge that professionals come to invent themselves as the keepers of expertise. Yet archaeology's professional status depends upon a range of participants – with their differing skillsets and specialties – to sustain itself today. As Carr (2010) notes, on the ground, expertise is born out of its enactment – in its gestures, its spoken words, its apprenticeship of new workers, its engagements with people outside the institution, its application of different forms of specialized media, etc. In other words, it is always in a state of evolution.

Historical Background

To tell the history of archaeology's professionalization is to trace back to the first recorded instances of collecting practice, where individuals begin to gather demonstrably old objects with an eye towards establishing their age, interpreting their function, and placing them on display (either for personal or wider consumption). Some date such practice to at least 2000 BCE in Egypt, Mesopotamia, and China and suggest that it was often accompanied by attempts at excavation work (Schnapp 2002). The unearthing of unexpected assemblages from prehistoric sites has led to further speculation that humans across time and space have always had a tendency to invest in collecting activities (Schnapp 2002). Others, writing more targeted, method- and region-specific histories of archaeology, situate the earliest excavations in Britain, for instance, to Medieval times (c. 1190) as devotees sought to substantiate the presence of saints or confirm Arthurian mythology. However, it is collecting and work with collections, above any recognizable form of fieldwork, that became the breeding ground for archaeology's emergence (also see Lucas 2001).

In all cases, these activities were pursued by varied individuals not discernable as modern-day archaeologists. Indeed, the entire conceptual and methodological basis for, as an example, prehistoric archaeology arguably derived from heterogeneous practitioners (e.g., clerics) and cognate fields – geology, anthropology, and paleontology (which were themselves all in a state of emergence) – especially across the nineteenth century. Hence, the concept of a professionalized prehistoric archaeology was effectively nonexistent until approximately 100 years ago. However, what is critical is that the roots of such professionalism lie in the systematization and relationships between people and things that grew out of the earliest collecting activities. While these activities might be poorly documented in terms of their initial scope, by the time of the Renaissance, they had begun to proliferate in conjunction with growing trade, travel to the Western Hemisphere, more broadscale appreciation of history and artistic trends, and increasing pressure for individuals to conspicuously display their connections to such pursuits. A unique collection could testify to one's status, education, and networks of affiliation, with the consequence that collecting became a means of affirming the identities of a growing portion of the population.

The resultant assemblages of objects tended to be fairly encyclopedic in terms of their spread. They often included a range of specimens from around the world, some with medicinal or therapeutic properties, some Classical relics, and some purely curious, but all "valued for their intrinsic rarity, for the romantic echoes of the far-away and strange with which they tantalized the imagination, and, sometimes, for their aesthetic virtue and workmanship" (Pearce 1990: 20). Significantly, it was generally in grouping together these objects for showcasing in private spaces that they then became the testing grounds for systematic comparison, theory building, and explanation about the natural and cultural worlds. They were increasingly subject to labelling and categorization, usually according to the prevailing

conceptual paradigms of the time (e.g., animal-vegetable-mineral, earth-air-fire-water). From at least the sixteenth century onwards, concerted intellectual work on such collections expanded to the extent that some were supplemented with guidebooks or human guides in an effort to manage viewers' understandings of the materials. Similarly, some were moved out of single, private study rooms into larger galleries – what we might now identify as museum spaces – to allow more considered attention to the presentation and accessibility of the objects.

Concurrent with changes to this physical staging of collections, dissemination beyond the display space itself gained ground via the production of manuals, atlases, and catalogues of objects (e.g., Schnapp 2002; Moser 2013). Indeed, collectors began to invest in artists to record their own personal collections, document other collections of interest, or copy from preexisting collections in manuscripts. That illustrative practice itself was then increasingly refined, with depicted materials becoming more abstract and standardized to allow comparison and structured evaluation. In this sense, early gallery/museum work and illustrative work (circulated via published sources) ran in parallel, feeding back into one another as regards the construction of object types and the articulation of basic schemas for making sense of artifactual and other materials.

Publication is credited by many as the transformative force in crystallizing professional growth. As per Schnapp (2002: 137), it "provided the means of social and intellectual visibility of the antiquarian discipline." Arguably, however, this emphasis on publication perpetuates the long-lived tension in historically oriented studies to privilege textual outputs above material remains (for a recent discussion of this tension see Lucas 2012). At the same time, it distracts from the many related activities that fed into the building of archaeological communities. Where archaeology finds its bearings is in its privileging of the material, its attention to objects themselves, and in the collectivities (people and other artifacts) that form around these objects. Some see such focusing of attention on artifacts above text as a patently strategic move by interested individuals looking to carve out a distinct niche of practice (e.g., Lucas 2012: 22). Regardless of the intentionality behind it, from the seventeenth century onwards, propelled by Renaissance and emerging Enlightenment developments, an observable shift in concern towards material sources (away from purely literary sources) manifested itself (Moser 2013). More collecting led naturally into more contemplation of those finds; and opportunities for conversation about them were facilitated by the foundation of key learned societies (e.g., the Royal Society in 1660; the Society of Antiquaries of London in 1707) and the first public museums (see Diaz-Andreu 2007; Pearce 2007).

The latter are particularly important as they tended to be characterized by the movement of previously private collections into university or nationally sponsored galleries, making them accessible on a larger scale. Accordingly, these new spaces (e.g., the Ashmolean – the earliest public museum in the world – which opened in 1683 in Oxford, UK) became home to the same mixture of exotic specimens and antiquities once so integral to individual identity building. However, such collections continued to operate here in a similar fashion as before, yet at a larger scale – as resources for study *and* affirmations of institutional and national status. Classical objects, in particular, suggested a direct connection to revered cultures of the past, and as their institutional showcasing coincided with major colonizing activities around the world, we see these original collections expanded often as a result of federally sanctioned missions to elaborate them. Antiquities hence became embroiled in a nationalistic enterprise as states and major organizations sought to legitimate their standing (Diaz-Andreu 2007). This, in turn, fuelled further collecting and dedicated excavation work.

In concert with such institutional development, learned societies continued to grow. Despite their often ephemeral nature, these societies were indispensable to the cultivation of knowledgeable antiquarians, and they are now appreciated by some as the lynchpins of disciplinary development (e.g., Sweet 2004). They provided forums for individuals with shared interests to meet, correspond, exchange transactions, view objects (either

physically on display in meetings or illustrated in society publications), avail themselves of associated libraries, and otherwise generally "participate in the wider world of learning" (Sweet 2004: 81). Their networks were wide, spreading across Europe and European colonies into the Americas and Asia (Sweet 2004; Diaz-Andreu 2007). Some such societies were implicated in the establishment of the first major public museums (e.g., the Museum of the Society of Antiquaries of Scotland founded in 1780). However, they also manifested, for instance, in Britain from the early 1800s, in smaller literary and philosophical societies and county archaeological societies, where individuals who perhaps did not have the means to journey abroad (but who nevertheless shared the epistemological impulse to observe, explain, situate themselves in, and order the world around them) sought out local antiquities for their collections (Pearce 1990). Together, these societies helped to propel a trade in artifacts; and at the same time, they facilitated discussion about both the nature of the artifacts themselves and the most systematic means for acquiring them. As such, they were among the "circulation systems" (also including auction houses and dealers) key to supplying the material remains around which archaeology emerged (after Gosden and Larson 2007: 49, 52). Their interests fed into barrow digging and an increase in excavation activities, and their collections became showpieces for the wave of new museums that opened in the mid-nineteenth century. That wave (evident across Europe) was prompted in part by state concern to educate (and, arguably via such education, placate) citizens and in part by the success of great international expositions (Pearce 1990; Diaz-Andreu 2007). In Britain, for instance, such museums and related exhibitions promised a platform for "social reform and industrial progress," and their viewing became part of the recreational endeavors of middle class individuals (Gosden and Larson 2007: 37). On the ground, though, they were the seedbeds for honing the archaeological eye – that is, for breeding public recognition of an emerging field of artifactual study and for acting as convergence points for those articulating that study.

What is critical is that these museums often assumed a role equivalent to the scientific laboratory, with curators sometimes explicitly acknowledging their lab-like possibilities – where "ideas could be developed, tested, or discarded" (Gosden and Larson 2007: 63, in reference to the curator Henry Balfour's perception of the Pitt Rivers Museum). Like the manuals of antiquities published from the sixteenth century, museums offered room to experiment with concepts, refine categories, and literally institutionalize ways of thinking about the past based on observable materials. Such is true in the broader sciences as well, with some arguing that investment in scientific laboratories actually *followed* that of museums as sites for knowledge making. Either way, they seem to have provided the earliest solid infrastructure for archaeological work, with some claiming that the first dedicated chairs of archaeology were specifically employed with an aim towards training for museum, library, and archival work (Diaz-Andreu 2007). The Peabody Museum of Archaeology and Ethnology in the USA established in 1866, for example, has been credited with crafting "an institutional framework within which scholars could do scientific work" (Christensen 2011: 13). These spaces effectively set in place the first meaningful homes for archaeology, and it is significant that some of the most paradigmatic shifts in archaeological thinking came about via museum-based activities (see below).

While the earliest university post in archaeology is attributed to Uppsala in 1662, such positions were incredibly limited, and their holders tended to simultaneously occupy most other related posts in a given country (e.g., museum, governmental, and university-based) (Kaeser 2006; Diaz-Andreu 2007). In other words, these first professionals were often working in some isolation on all aspects of the antiquarian pursuit at once. Arguably, it was only as museums (and associated cultural institutions) exploded in the mid-nineteenth century that a genuine lack of sufficient specialists to fill related positions exposed itself, and hence, attention to formal means of outputting a competent workforce began to grow (Kaeser 2006). As Browman (2002) has noted, individuals such as the

American Frederic Ward Putnam (1839–1915), who held or established many of the foundational disciplinary appointments in the USA, were trained in a bespoke, apprentice-like fashion and tended to replicate such training in their own early practice. Here, again, the museum (the Peabody) was the staging ground for capacity building, and in conjunction with expansion of the museological collections, but without a formal student body for support, Putnam sought out connections with interested people around the USA via correspondence (Browman 2002). Akin to (if not indivisible from) the circulation systems of learned societies, this "correspondence school" of archaeology (Browman 2002: 219 citing Hinsley 1999: 144) allowed for exchanges of ideas and methods of collecting, recruitment of new people onto excavation expeditions to expand the collections, and acquisition of other personal collections. However, it also helped to demarcate the institution as the arbiter of knowledge making, as individuals then began to turn to institutionally sited practitioners to validate their finds and seek out further training. The advantage, as has been noted for prehistoric archaeology, was that these sites provided an opportunity to "put an end to the previous epistemological confusion," fostering common methodologies and harnessing the seeming authority of the institutional structure to "lay down the heuristic frameworks of the prehistoric science to come" (Kaeser 2006: 153).

Around Europe, the museum was long a driving force in the conceptual solidification of archaeology, as its collections offered the comparative materials necessary to think through chronologies and typologies, which themselves then supplied the fabric for pursuing further intellectual work. Base epistemological frames for archaeological thinking, such as Danish C.J. Thomsen's Three-Age System, were developed and elaborated specifically in the museum environment on collections that were then put on display for visitors and, in their showing, thereby subject to more interrogation. The British-based General Pitt Rivers' typological-evolutionary take on human history and the contrasting culture-historical approach of the US-based Franz Boas (Gosden and Larson 2007) were similarly articulated and debated through active negotiation of collections in museological/display spheres. These same museums often stood as the first lecture spaces for concerted teaching of archaeology, and as per above, their growth in numbers over the course of the nineteenth century subsequently led to a demand for qualified practitioners to take over new managerial and curatorial posts. In tandem with museum work, related heritage institutions began to spread across Europe in the mid-to-late nineteenth century – part of the same ideological drive to unite and propagate identity on a national and regional level (Kaeser 2006). The British predicament, where "demonstration of a preservation ethic came to be seen as a hallmark of a 'civilized' nation" (Emerick 2003), had currency abroad as well, leading to the establishment of governmental posts and associated protective legislation for historical places and monuments and further pushing on the demand for qualified workers (Kaeser 2006). This meant that institutional attention then began to be turned towards producing such workers, leading to the articulation of university-based accreditation in archaeology around the turn of the twentieth century (see below).

From the perspective of professionalization, therefore, it is at this point that archaeology had the scaffolding in place to elaborate a disciplinary culture. Indeed, it follows a general trend evident across the sciences in the late nineteenth century towards increasingly professionalized practice. By this time, foundational concepts had been articulated, some basic procedures for studying material culture were under development, and an authoritative base centered especially in the museum was in place to support the ongoing activities of the community. Expertise in the methodology of excavation itself arguably played a marginal role in the beginnings of archaeology (Lucas 2001), as it tended to be from the observation and handling of objects (directly or indirectly through visualizations), site visits, conversation and sharing of resources, and subsequent intellectual exercises in classification and schema construction using collected materials that the basic infrastructure for the discipline emerged.

While institutionally recognized "professionals" were few and their activities extensive, their connections to learned societies and other productive people, places, and materials (e.g., collections) together created the architecture for the professionalization of the field. These same individuals were often directly linked to the development of the first discipline-specific periodicals and to major congresses and conferences that brought interested people together under increasingly formalized circumstances. Some such circumstances, such as the International Congress of Anthropology and Prehistoric Archaeology (*Congrès international d'anthropologie et d'archéologie préhistoriques*), founded in the 1860s, were among the earliest transcontinental networking spaces, where hundreds of individuals with varying levels of expertise could gather every year or so to discuss emerging knowledge and techniques. With such communities of practitioners thus in place, it was with the ensuing development of a rigorous educational structure (for outputting sufficient workers to satisfy demand) that the professional archaeological industry coalesced.

Key Issues/Current Debates

It is the twentieth century and beyond that perhaps represents the most controversial stage in archaeology's solidification, arguably because consideration of this timeframe has been less concerted and consistent. There is general agreement that it is distinguished by the emergence of university-based expertise, which effectively sets in place a self-perpetuating cycle for the discipline – yielding students specifically trained in "archaeology" who then seek archaeological employment at organizations which scout out that very brand of institutionally sanctioned archaeological knowledge. Some see this period as the second phase in the institutionalization process (Kaeser 2006) – wherein the ensconcing of archaeology in academia provides for its "anchoring in the long term," apart from the often ephemeral constitution of societies, congresses, journals, and even museological institutions in the nineteenth century and before. As per above, scholarly departments of archaeology sometimes evolved out of preexisting museum spaces, at the hands of enterprising specialists, and/or even out of the remnant collections of international expositions (e.g., see Browman 2002). But the growth of the archaeological education business is subject to debate, with suggestions that for most of the early twentieth century, student numbers were minute and employment opportunities comparable. Emerging research hints that the situation was more complex and that the tendency to reduce twentieth-century archaeology to academia alone deserves to be questioned. In Britain, for instance, 1 year after its official launch in 1937, London University's Institute of Archaeology was outputting upwards of 100 students per year in a rigorous, laboratory-oriented archaeological style taught by many of the leading practitioners of the time (Perry 2011). This institution was simultaneously invested in the design and dissemination of major archaeological exhibitions, which were advertised across the country, attracting a viewership that numbered, in some cases, in the thousands. It is also linked to the earliest British television broadcasts of archaeology, which evolved over time to become crucial means of publicizing, attracting support for, and recruiting new pupils into the discipline. Even in the late 1920s, individual archaeology classes run through University College London saw registration of c. 20 students each (predominantly, if not fully, female); and major excavations at sites such as Maiden Castle in the 1930s embraced 100 or more students and assistants per year, with thousands of visitors and tens of thousands of related souvenirs and publications sold (Perry 2011). Moreover, extramural education in British archaeology had its origins as early as the 1940s, and dedicated excavation training schools are documented from at least the 1930s.

Across Europe and North America, such disciplinary growth continued, propelled in particular by the Depression and World War II. In the USA, the former led to government investment in archaeological practice to assist with job creation, thereby fuelling a need for trained workers (Patterson 1999). In Europe, the latter resulted in regeneration efforts (both historical and industrial), ultimately manifesting in documentation work and rescue archaeology that demanded the

labor of dedicated commercial archaeological units and associated volunteers (Roskams 2001), again fuelling university enrollment numbers. What is critical for professionalization is that, in all cases, post-WWII is marked by increasing specialization within the discipline as the nature of practice extended itself; an escalating codification of such practice, with the publication of further manuals and textbooks and the drafting of the first codes of ethics; growth in the number and variety of professional organizations, which carry on the networking and convergence functions of earlier learned societies and which themselves continue to contribute to disciplinary codification and publication; greater legal and legislative attention to the nature of archaeology owing to its ballooning relationship to city planning and industrial development; and heightening stratification within the archaeological workforce, generating a full spectrum of laborers – from itinerant fieldworkers to interested volunteers, to full-time unionized staff, office-based professionals, academic elite and transient lecturers (Patterson 1999; Roskams 2001).

Importantly, then, the makeup of the discipline is seemingly no more uniform today than formerly; and the long-standing argument that so-called amateurs have been displaced from archaeology is highly debatable. Key museological collections have been birthed out of, and continue to be amplified by, donations from a range of contributors (both accredited specialists and not) (e.g., Gosden and Larson 2007); excavations still rely on volunteer efforts; and funding for practice is often tied directly into broader public impact. Many people, sites, and materials have always and collectively been indispensable to the cycle of disciplinary knowledge construction. What has changed over time, therefore, is arguably no more than the number of people and things involved and the means by which they are organized and classified.

International Perspectives

Outside of Euro-America, the professionalization process for archaeology has followed a similar path, although there is evidence from both Japan and China that robust antiquarian enquiry and publication (e.g., in the form of antiquities manuals) might have emerged much earlier than in Europe (Schnapp 2002; Lozny 2011). Critically, however, from approximately the nineteenth century onwards, a general trend presented itself of concepts and methodologies spreading from Euro-American institutions abroad, either via movement of Euro-American-trained practitioners to foreign locations (not infrequently in association with colonization ventures) or via training of foreigners at Euro-American institutions followed by their return home to apply such training domestically (see contributions in Lozny 2011). Regardless of the direction of their movement, once ensconced internationally, these various practitioners participated in the production of region-specific terminologies and typologies, societies, journals, and all those related disciplinary constituents that come to form the anatomy of a distinctive professional culture. Their links to Euro-America also worked to facilitate wider exposure for local research and to cultivate systems of patronage on a worldwide scale, which, in turn, fed back into the ongoing validation and scaffolding of archaeological practice overall.

Future Directions

Professionalization is an ever-evolving process, meaning that its study is continuously open to elaboration. Indeed, focused attention on the professionalization process in archaeology is still rare, making the scope for further enquiry relatively vast. Growing attention to institutional histories has been among the catalysts for reconsideration of the constitution of expertise in archaeology (e.g., see Kaeser 2006; contributions in Pearce 2007). This work is complemented by recent fine-grained oral historical research (e.g., interviews with current and retired practitioners), as well as gender-oriented studies of the discipline, and concerted interest in all those "forgotten" participants in archaeological knowledge making whose contributions have played into the everyday articulation of the field of practice, yet whose names have generally been eclipsed by the "great" archaeologists

documented in typical disciplinary histories (Smith 2009). Those elements of archaeology that make it seem a coherent subject matter – that supply it with a professional air and an expert identity – are similarly seeing greater deliberation, including research into how archaeologists dress, observe the world around them, and speak and conduct themselves in the field.

As noted by Gosden and Larson (2007: 151), the term "discipline" "implies an attempt to contain and control something that is essentially unrestrained." Such has always been the nature of archaeology: a multipronged, composite pursuit that now stands apart as an accredited profession but that has always impinged upon other specialty areas, drawn on methods from a variety of fields, attracted contributors from comparably varied spheres of interest, and attended to materials from all times and places of human existence. Accordingly, perhaps the most productive line of study today is research into the networks and movements of people and things across the boundaries of archaeological practice – i.e., enquiry into precisely that set of messy connections and exchanges that has rendered the discipline into something recognizable (e.g., Gosden and Larson 2007). Archaeology, as it is advocated today, is not only a specialist intellectual endeavor but so too a platform for transferable skill development applicable to a range of other fields. In this respect, the boundaries of the professional community are ever-swelling, and the individuals and objects that come together to make it possible and legitimate are likely to continue to challenge its dimensions. Thus, while diverse concerns for the human past may have been consolidated over time into a distinct form of expertise, the professionalization process itself suggests that the nature of that expertise will never be stable.

Prospection Methods in Archaeology

Steven A. Schmich
Archaeological Research Institute, School of Human Evolution and Social Change, Arizona State University, Tempe, AZ, USA

Introduction

The Third Age of Discovery that helps define our modern era is based on remote sensing and the geophysical inventory of earth largely made possible by advancing technologies (Pyne 1988: 190, 1998: xi). This includes much of

the new territory archaeology explored in the late twentieth and early twenty-first centuries. However, it is important to note that for all the technical innovations of geophysical method and satellite imagery, archaeology remains a discipline of and about people. Archaeology is about understanding what it means to be human and increasingly about marshaling the record of tens of thousands of years of human decision-making to deal with the challenges we face today. But this requires that archaeologists be able to look beyond the obvious and not be limited to what is apparent on the surface – by any definition. What the new technologies of prospection have added to archaeology's repertoire is a glimpse into the "inhuman geography" (Pyne 1998: xi) of our human past, the places where we cannot go or where experience indicates that we defer going by more traditional methods like excavation. Necessarily, these technologies have evolved alongside dramatic increases in readily available computer power that allow us to process and find the meaningful patterns among incoming multitudes of new information.

Data collection continues to be the most straightforward element of archaeological prospection with days often required to process the data collected in a few well-spent hours (Conyers 2010: 122). The published record is noticeably weighted toward case studies demonstrating a particular method's applicability and use, although a trend toward case studies applying archaeological prospection techniques directly to test hypotheses of human behavior has increased since c. 2000. This is tempered by the fact that archaeological prospection is still largely the realm of geophysicists rather than archaeologists per se and that results are perhaps too frequently presented in geophysical rather than archaeological terms. High initial cost relative to traditional forms of archaeological survey plays a major role in determining whether prospection can be included in a project (Jordan 2009). Nevertheless, the results of archaeological prospection, in all its forms, are becoming "a primary data source from which to study the human past" (Conyers 2010: 119).

Definition

Remote sensing began as a collective description referring to both geophysical and imaging techniques. That usage continues (e.g., see papers in Johnson 2006a). With the introduction of *Archaeological Prospection* in 1994 as a peer-reviewed journal covering "the use of a wide range of prospecting techniques, including remote sensing (airborne and satellite), geophysical (e.g. resistivity, magnetometry) and geochemical (e.g. organic markers, soil phosphate)" (Archaeological Prospection 2011), archaeological prospection became the preferred collective term. Remote sensing explicitly refers to satellite and other forms of reflective imagery (e.g., infrared spectral analysis). As geophysical methods become familiar fixtures in the journal literature, they are named and recognized outright by the specific technique employed (e.g., ground-penetrating radar, cesium magnetometer, etc.).

Key Issues

Archaeological Prospection Methods

The four most widely applied techniques of geophysical prospection are ground-penetrating radar, electromagnetics, magnetics, and earth resistance (Conyers and Leckebusch 2010: 117).

Ground-Penetrating Radar

Ground-penetrating radar (GPR) uses nondestructive electromagnetic waves to locate buried targets or interfaces (Daniels 2005: 1833). A GPR transmits a regular sequence of low-power packets of electromagnetic energy into the material or ground and receives and detects the weak reflected signal from the buried target. Under most conditions, ground-penetrating radar is capable of measurements up to a few meters deep. However, specially adapted systems operating in optimal circumstances can sometimes penetrate up to hundreds of meters. Unlike atmospheric radar, the signal from ground-penetrating radar is subject to being absorbed as it travels down and back through sediment layers. Although the method works well in some solids like granite and ice, it

cannot be used effectively in clays with a high salt content, or even saltwater, because these materials drain the signal's electromagnetic energy (Daniels 2005: 1833).

Ground-penetrating radar is especially valuable in deeply buried and stratigraphically complex contexts because it can discriminate important layers and map only specific levels or horizons. This type of complex stratigraphic analysis is usually impossible using other geophysical techniques (Conyers 2010: 183). Results from ground-penetrating radar are compatible with data from more traditional archaeological methods. Such data lend themselves well to a quantitative and scientific approach for understanding the human past.

Electromagnetics

Electromagnetic surveys are a quick way to locate and map large earth features such as leveled mounds and refilled ditches. They work especially well where the surface soil is dry, hard, or rocky or where the vegetation is moderately dense. As in all geophysical techniques, for electromagnetic surveys to be successful, it is necessary that the archaeological features sought are different enough from the surrounding terrain to register (Bevan 1983).

Electromagnetic instruments use conductivity measures that quantify how materials react when exposed to an electromagnetic field (Bevan 1983; Conyers et al. 2008). The method can be used to explore a range of depths; however, with the instrument carried at about hip height, sensitivity to materials suspended in sediment layers is generally most accurate down to 1.5 m. Depending on field conditions, useful readings are possible from about 1.5 m to about 5 m and then decreases until it is no longer within the instrument's depth range, about 5–6 m (Conyers et al. 2008). There have been claims that electromagnetic instruments can produce independent readings from multiple depths, but to date, these readings have not proved reliable in field tests (Conyers et al. 2008). Soil moisture, stratum thickness, geochemical variation, and changes in the amount of organic material present can all affect electromagnetic readings. Portability in the field and accuracy within its optimal parameters continue to make electromagnetics a favored geophysical method for archaeologists. In experienced hands, it is possible to obtain high-resolution electromagnetic survey data as fast as a person can walk in the field (Wynn 1986).

Magnetics

Magnetometry is one of the most productive and certainly one of the most often applied geophysical methods in archaeology. "(I)t is almost as if nature designed archaeological sites to be made visible by the magnetic variations they exhibit" (Kvamme 2003: 441). Primary among these magnetic variations are:

Soil heated past the Curie temperature – the point at which magnetic materials undergo a sharp change in their magnetic properties (beginning at about 570 °C for the mineral magnetite). Hearths, earthen ovens, kilns, and structure fires can disrupt the spontaneous arrangement of elements in rocks, minerals, and sediments, replacing it with a more general magnetic behavior. The resulting intensified magnetic field is restricted to the heated area. Magnetometry identifies this localized, burned zone. Archaeologists still must ascertain whether the heat source was natural or the result of human behavior.

Fired artifacts, especially ceramics, adobe bricks, and fire-hardened daub, create an identifiably intense magnetic field in the same way as discussed above for natural materials.

Magnetic susceptibility can also be a natural occurrence created by the inclusion of magnetizable materials in the composition of soils, sediments, rocks, etc.

Long-term human occupations of an area can increase the magnetic readings of surface layers when compared to underlying natural layers. The same discard behaviors that help create the archaeological record also introduce fired materials (i.e., ceramics) into the upper soil layers of a site. Such magnetic readings can be a way of locating midden areas. Reverse processes that remove magnetically enhanced upper layers in identifiable patterns, digging ditches or pit houses, for example, provide equally valuable data for archaeologists to analyze.

In the case of sites with coursed wall architecture that has become buried over time, magnetometry readings can identify building materials that are either more or less magnetic than the natural layers of overburden and surrounding sediments.

And the process of smelting metal artifacts, as well as the metal artifacts themselves, produces identifiable anomalies in the surrounding natural layers.

Magnetometry is most successful in locating identifiable anomalies in the first two meters of sediments or soils. However, larger objects (a stone building foundation as opposed to a ceramic sherd) emitting a stronger signal can be detected at lower depths. Magnetometry is "the work-horse of European archaeo-geophysics" (Kvamme 2003: 441).

Earth Resistance

In an earth resistance survey, electrical current is emitted into the ground; as it radiates out in an even wave, any inclusions interrupting the relative uniformity of the sediment layer will alter the resistance to current patterns in measurable ways. Mapping these variations by stratum can help locate buried archaeological remains (Schmidt 2009: 67), although cultural features must still be separated from natural features using another means, like excavation.

When electrical current travels through copper wiring, the charge is carried by freely moving electrons. Since these electrons are traveling in a closed circuit, they neither deplete nor accumulate – the electrons constantly flow through the circuit loop. However, electrical current traveling through natural soils is carried by ions, not electrons. These charged particles are created when salt crystals in the ground break down in the presence of water. Any obstacles to the movement of these ions in the ground that cause a weakening of the current are called the soil's electrical resistively (Schmidt 2009: 68). Ultimately this electrical resistivity is a function of the amount of salts in the soil. There are some salts in all soils, which makes the method viable, but the concentration of salts (and therefore the conductivity/resistivity available to carry the current and be measured at the surface) varies by soil type. Moreover, electrical resistivity depends on the presence of water in the soil to dissolve the salt crystals and transport the residual ions (Schmidt 2009: 68). Resistivity decreases as water becomes ice or soils dry out in arid conditions. The presence and position of water in the soils depends on the size of sediment grains and the spaces between the grains. Water is needed to dissolve the salts into their constituent ions.

Resistivity is the opposite of conductivity (see "Magnetics" above). Earth resistance methods are sensitive to subsurface contrasts caused by resistant natural rock formations and by resistant cultural formations like stone walls. They also can note less obvious variations in soil and sediment layers (Kvamme 2003: 441–2). Soil resistivity is measured through contact probes spaced from 0.25 to 2 m. The spacing between probes controls prospecting depth beneath the surface. When several depth settings are employed within the same area, three-dimensional data acquisition and volumetric computer imaging are possible (Noel 1992; Szmanski & Tsourlos 1993; Walker 2000 – as cited in Kvamme 2003: 442). Magnetometry (conductivity) and earth resistance methods are popular in European archaeology.

Metal Detectors

The most controversial issue concerning geophysical technology for archaeological purposes is the use of metal detectors by interested amateurs, who are often well-intentioned, but sometimes not. In archaeology, the value of artifacts is based on the information they provide. The problem with metal detectors arises when they are used to pull artifacts from the past we hold in common to be sequestered in private collections or when the value of artifacts is based solely on the money they may bring in exchange. Metal detector use is a complex issue that involves property rights, antiquity statutes, and international laws.

Great Britain has the most experience with interactions between research archaeologists, cultural resource managers, and metal detector enthusiasts. A 1995 survey by the Council for British Archaeology found that of the thousands

of artifacts recovered by metal detector enthusiasts each year, only a fraction was reported to museums in England. Between 1988 and 1995, illicit metal detector use damaged some 188 archaeological sites that were protected by law (Hunt 2011), and three-quarters of the archaeological excavations in England had experienced "raids" by metal detector users (Hunt 2011).

What appears to offer the most success in resolving this dilemma is a training program that gives interested enthusiasts a way of contributing to the greater body of archaeological research as avocational archaeologists. They agree to follow a code of conduct in return. It is not a perfect system – ethical questions still exist about "whether it is right to amass personal collections of material inaccessible to more detailed research, or to sell such collections on the open market" (Hunt 2011). There are also concerns that the payment of rewards for "treasure" finds sends the wrong message. Including a place at the table for trained avocational archaeologists may help abate at least one of the modern threats to the archaeological record.

Satellite Imagery

Satellite imagery is the latest incarnation of aerial photography, which is reputed to have started with Gaspard-Félix Tournachon, a French photographer, who took pictures of Paris from a balloon in 1858. By World War I, aerial photography was being used by the military to map battlefields and to gather information.

Space-based images of our Earth also began with military applications and as a means of information gathering – in this case highly classified information gathering for intelligence agencies. As the existence of satellite images became more widely known, and as their availability became less exclusive, applications widened to include tracking global weather patterns, tectonic activity, surface vegetation, ocean currents and temperatures, polar ice fluctuations, pollution, and eventually archaeology during the concluding decades of the twentieth century. Archaeologists are still finding new ways to use the full range of analytical tools available for assessing satellite image data of the earth's surface and subsurface (Parcak and Mumford 2011). Decreasing costs, increasing image resolution, and on-line Internet availability are speeding this process along.

Satellites collect images from hundreds of miles above the Earth's surface. The altitude from which an image is taken, and the physical characteristics of the sensor used, determine the amount and the type of detail available from a satellite image (United States Geological Survey [USGS] 2011). For example, color-infrared images record energy from portions of the electromagnetic spectrum not visible to the human eye. Near-infrared light reflected from the recorded scene appears as red, red appears as green, green as blue, and blue as black. As a result, color-infrared can differentiate between types of vegetation and bodies of water (United States Geological Survey [USGS] 2011). Importantly for archaeologists, it can also penetrate the atmospheric haze that has become a defining characteristic of modern urban areas.

Much of the credit for first recognizing the potential of multispectral imagery in archaeology goes to George Gumerman and Theodore Lyons (Parcak 2009). Their 1971 paper Archaeological Methodology and Remote Sensing (*Science* 172 [3979]: 126–132) moved the state of the art beyond identification and simple interpretation to the types of pattern recognition that are the basis for what has come to be called satellite archaeology (Parcak 2009). Even at an early date in the use of enhanced imagery, Gumerman and Lyons noted what has become axiomatic today: each archaeological site will have its own spectral properties, and, therefore, archaeological prospecting can rely on no single imagery format (Parcak 2009).

In 1972, one year after Gumerman and Lyons' groundbreaking publication, the United States launched its first Earth Resources Technology Satellite, ERTS-1, later renamed Landsat 1 (United States Geological Survey [USGS] 2011). The Landsat series gathered data from sensors measuring a range of wavelengths of electromagnetic energy reflected or emitted from earth – and demonstrated the actual potential satellite imagery holds for archaeology. Landsats 1–5 carried the multispectral scanner (MSS) sensor with a

resolution of about 80 m (260 ft). In 1984, the year NASA launched Landsat 5, the United States Congress directed the National Oceanic and Atmospheric Administration (NOAA) to find a commercial vendor for its Landsat 6 project. That satellite, developed by the Earth Observation Satellite Company (EOSAT) under a U.S. Commerce Department contract, failed at launch in 1993 (National Aeronautics and Space Administration [NASA] 2011a: NOAA press release 95–13). The launch program returned to NASA, and Landsat 7 successfully lifted off in 1999. The last of the series, Landsat 7, carried the Enhanced Thematic Mapper Plus sensor that replicated the capabilities of the successful Thematic Mapper instruments on Landsats 4 and 5, and included features for global change studies, land cover monitoring, and mapping larger areas than its predecessors (National Aeronautics and Space Administration [NASA] 2011b).

As this is written, "(t)he evolution of satellite image technology is. . .enabling the manipulation of a greater range of data contained in increasing types of satellite images (e.g., Aster; Corona; Landsat TM, etc.): archaeologists can now examine a broad spectrum of reflectivity signatures and bands within and between archaeological sites, including both surface and sub-surface features" (Parcak and Mumford 2011). For example, combining multiple analytical techniques to detect the vegetation signatures within a satellite image of the El-Markha Plain on the Sinai Peninsula of the Middle East made it possible to identify and isolate water sources within the overall arid environment of Sinai, which in turn revealed potential archaeological sites for surface assessment (Parcak and Mumford 2011). Multispectral satellite data have also allowed archaeologists to model dynamic landscape processes in the Mediterranean Basin (Barton 2004) as well as define survey areas in Spain and statistically eliminate areas of erosion from the survey area (Barton et al. 2002, 2004).

Tools and datasets like Blue Marble from the National Oceanographic and Atmospheric Administration (NOAA) (see http://sos.noaa.gov/datasets/Land/bluemarble.html) and the multiple platforms of Google Earth™ (see http://www.google.com/earth/index.html) have helped to demystify satellite imagery for non-specialists.

Light Detection and Ranging

Light detection and ranging (LiDAR) represents something of a return to the aerial photography origins of remote sensing – with important differences. LiDAR scans the land surface from an airplane or helicopter with a high-frequency pulsed laser beam. By timing the laser signal from transmitter to receiver, LiDAR can determine distance and thus take rapid measures of surface elevation. When combined with Global Positioning System (GPS) coordinates and an inertial navigation system (INS) to account for airplane movement and hold the airborne transmitter constant, LiDAR readings produce high-resolution digital elevation models (DEMs; see geographic information systems [GIS]) of the landscape below (Hesse 2010). What sets LiDAR apart is that its laser signal can be filtered to record only the last return pulse of the laser beam, making it possible to create DEMs of the landscape underneath a rainforest canopy of vegetation (Hesse 2010; Chase et al. 2011). LiDAR-derived data accurately portray not only the topography of the landscape but also structures, causeways, and agricultural terraces with a low relief of 5–30 cm (Chase et al. 2011: 387). Large-scale mapping projects in archaeology have always been costly and time-consuming when using traditional methods. This is especially true in off-the-beaten-track locations and rugged terrain where the modern world has tended to leave viable archaeological sites undestroyed if only rarely untouched. In such conditions, swath mapping with LiDAR (overlapping flight paths that can be integrated together) is a powerful and cost-effective tool.

International Perspectives

Although geophysical and satellite imagery as methods of archaeological prospection are used nearly everywhere in the world where archaeology is a recognized discipline, not all working archaeologists have a positive view of such

means. Nor should archaeologists be expected to hold generally uniform views. The modern practice of archaeology lies at the nexus of the social, natural, and physical sciences – with archaeologists varying the degree of emphasis in their approach between the three. Philosophical and operational tensions in the sciences are often beneficial. Thomas Kuhn, the historian of science who introduced the concept of "paradigm" into post-1960s discussions of science (Kuhn 1962/1970), considered such friction to be the essential tension (see essays in Kuhn 1977) that led to scientific accomplishment and greater understanding of the world around us.

Reservations about technological prospection in archaeology include the expensive cost of the instruments and software necessary to collect and process data; the additional training demands and access to that training, both of which can restrict availability in some cases; and a less than full understanding of the conditions under which the various instruments are likely to produce useful results (Johnson and Haley 2006: 35). Opinions vary as to whether we always apply the most applicable methods for each set of circumstances or whether we tend to rely on the methods we know. Archaeologists understand that geophysical and remote sensing are part of the hard work of gathering data and learning what the data may tell us about the human career. Our level of understanding may not always keep pace with the technology we are able to produce, and archaeologists constantly remind themselves that while new methodology often helps us to see in more detail, actual understanding remains grounded in our traditional commitment to hard work. Archaeology is deeply rooted in a profound respect for the men and women who created the past that has made our moment possible.

It is natural for observers interested in archaeology to wonder whether what may seem like a sudden burst of emphasis on remote sensing could be adding to a sense of remoteness from the humanness of the people who lived the past. "Spectacular images... may convey the impression that most 'good' geophysical surveys... leave little to the imagination.... In fact, well-executed surveys often yield useful results that are not immediately interpretable by many archaeologists" (Hargrave 2006: 269).

Data fusion (Kvamme 2006; Ernenwein 2009) is one of the most important concepts to develop from our growing body of experience with geophysical methods. Data fusion integrates the outcomes of multiple geophysical methods in one study area and applies their combined potential toward an improved understanding of the subsurface. As noted above, each individual survey method comes with its own strength and weaknesses. Integrating information from a number of methods allows the strength of one method (or methods) to compensate for any shortcomings in another. Integrated data can show the relationships between conductive, resistant, magnetic, and thermal noted subsurface anomalies and use this multiple recognition to enhance overall interpretations (Kvamme 2006: 15).

Excavating offers archaeologists a tactile perception of the artifacts in an assemblage. Data fusion offers a roughly similar multisensory insight into an entire subsurface region while including and preserving the surrounding context that we lose in excavation. It is an iterative process. The more often research programs include data fusion, the better at it we become. Integration can yield an end understanding beyond the capability of any discrete method alone (Kvamme 2006: 15). Applying multiple methods of data gathering also results in a broader array of data presentation – some of which are more visual and some more quantitatively interpretive or predictive. All of which, when fused together, offer a more complete understanding of the archaeological record without altering or destroying any irreplaceable part of that record.

Among the great challenges of archaeology, as usually practiced, is the pressure to get everything right the first time. Excavation is the best-known and most frequently employed means of gathering archaeological data. Archaeological excavation, digging, destroys the context that helps confer meaning to artifacts as it proceeds. "(T)he value of archaeogeophysical methodology with its inherently nondestructive nature speaks for itself. Researchers... now have the potential to recover detailed archaeological information from sites –

small and large – without destroying them" (Lockhart and Green 2006: 29). Archaeological prospection offers a way to assess the information value of subsurface material and factor it into a decision of whether or not to dig. We can make informed choices to leave non-threatened archaeological material in the ground and reserve it for future archaeologists whose methodology, presumably, will be even better than ours. Cultural resource managers can potentially use geophysical methods to mitigate the presence or absence of subsurface archaeological material for entire swaths of the right-of-way for pipelines, roadbeds, etc., as opposed to relying on surface surveys with test pits or backhoe trenches to sample the subsurface strata, although it must be noted that the effectiveness of geophysical methods in archaeology has not yet been "fully acknowledged in the laws, regulations, and standards that guide cultural resource management practices and excavation strategies" (Lockhart and Green 2006: 17).

Future Directions

The equipment used in geophysical applications was not developed with archaeology in mind. The satellites gathering multispectral imagery of earth were not funded by archaeology, nor were they launched at the request of archaeologists. As is vital for a constantly evolving discipline at the nexus of the social, natural, and physical sciences, archaeologists are adept at making use of the tools available. It seems reasonable that future developments are more likely to come in the form of increasingly sophisticated data-analysis techniques than in the data gathering equipment we have borrowed from other fields. Hopefully, the staged iteration wherein remote sensing results guide excavation results and excavation results help to refine the remote sensing (Johnson 2006b: 316) will increase in pace.

It is a near certainty that the pace of construction development will continue to impact the archaeological record; the questions we ask of the past will increase in complexity as we continue to look for ways of "treating the world as if we intended to stay" (Gray et al. 1993: 280); and the funding dedicated to archaeological research will continue to vary in amount and priority as a function of economic considerations in the immediate present. All of which make developing effective and efficient methods of archaeological discovery, definition, and analysis increasingly imperative (National Park Service – National Center for Preservation Technology and Training [NPS NCPTT] 2007). In this context, the time and energy archaeologists are devoting to geophysical and imagery-based methods of archaeological prospection seem more well spent all the time.

Proton-Induced X-Ray Emission Spectroscopy (PIXE): Applications in Archaeology

Rachel Sarah Popelka-Filcoff
School of Earth Sciences, The University of Melbourne, Melbourne, Victoria, Australia

Introduction

With the advent of nuclear-based analytical methods in the last 50 years, particle induced X-ray emission (PIXE) has established a role in the elemental analysis of archaeological material

and cultural heritage. PIXE is a technique with a diverse array of applications in biology, geology, materials science, and others and has found valuable wide-ranging applications in archaeology and cultural heritage research. Such applications for archaeology and museum work generally fall into the categories of compositional analysis, provenance, understanding surface treatments and changes, and conservation and restoration.

Definition

The general definition of PIXE is "particle-induced X-ray emission" although this is often synonymous with "proton-induced X-ray emission," which is a specific type of PIXE. Charged particles typically used in PIXE include both protons (p) and α-particles (He^{+2}). Protons are produced in particle accelerators such as Van de Graff instruments, whereas radioactive sources produce α-particles for PIXE (Johansson and Campbell 1988).

Most laboratories use an accelerator to create a beam of high-energy (1–4 MeV) particles. The sample is bombarded by a beam of these particles, resulting in ejection of inner-shell electron in the sample, followed by the de-excitation of the ion. Electron rearrangements then occur within the atom to fill the resulting vacancies, resulting in emitted X-rays and Auger electrons. The emitted X-rays have specific energies particular to energy transitions in a specific element; the number of X-rays emitted is proportional to the original concentration of the element of interest in the sample. Detection and energy sorting of the X-rays is primarily done using energy dispersive systems with semiconductor detectors and multichannel analyzers (MCAs) (Ehmann and Vance 1991).

Some advantages of PIXE for art and archaeology include its nondestructive elemental analysis capabilities with appropriate experimental setup, and simultaneous elemental analysis. PIXE has a large dynamic range from parts per million to percent range, and therefore is capable for trace, minor, and major elemental analysis. Elemental characterization of samples provides data for interpretation on artifact composition, technology, and origins. The technique has high sensitivity (1–10 ppm) for elements with atomic numbers in the ranges $11 < Z < 32$ and $75 < Z < 85$ (Johansson and Campbell 1988). In addition to trace analysis, PIXE is also capable of measuring major elements in the sample (up to percent levels). PIXE is a near-surface analytical method that analyzes the first 1–10 μm of a sample, which makes it ideal for analysis of thin layers of pigments or other surface treatments on artifacts. Depending on the experimental setup, it is also possible to collect data on depth profiling of elements in the sample using a related method, Rutherford backscattering (RBS). As compared to XRF, PIXE generally has a higher rate of data collection and less background spectral effects, due to lower Bremsstrahlung interactions and Rayleigh and Compton scattering. The technique is regarded to have high precision and reproducibility. PIXE often has relatively quick analyses times on the order of minutes (Johansson et al. 1995; Taylor et al. 1994).

PIXE was first developed in the 1970s. Over the next decades, the technique developed along with accelerator facility and electronics technology and is now a mature radioanalytical method with applications in many fields. Sample types in the early uses of the technique included ceramics and metals and have since expanded into varied artifact types such as glasses and pigments.

The majority of PIXE analyses are performed in the external beam configuration. Many standard PIXE systems produce a beam of around 1 mm diameter. Some modern systems now have the capability of micro-PIXE through beams 1 micron in diameter, which allows for spatial resolution analysis over small areas by rastering the beam over the sample. Micro-PIXE may also be used to analyze single spot areas or crystals in a sample.

Most facilities perform PIXE under vacuum; therefore the sample must fit in the dimensions of the vacuum chamber. However, extraction of the beam from the accelerator allows in-atmosphere PIXE analysis, which is advantageous for samples that otherwise may not be placed under vacuum.

Several facilities routinely perform PIXE. The major laboratories in this area are AGLAE in the

Louvre, (Paris, France), the STAR accelerator facility at ANSTO (Australian Nuclear Science and Technology Organisation) (Lucas Heights, Australia), and the University of Guelph, (Guelph, Canada) and the University of Kentucky (Lexington, Kentucky, USA), as well as others worldwide. More recently, the COBRA project in Italy has developed a 3–7 MeV pulsed proton beam towards the analysis of ancient artifacts (Vadrucci et al. 2017) Of these, AGLAE in France is the only facility dedicated to analysis of cultural heritage materials (Calligaro et al. 2003; Dran et al. 2004).

Recently, the PIXE technology has been adapted to portable technology (Pappalardo et al. 1996, 2003). These systems use radioactive sources to irradiate the sample with alpha particles and Peltier-cooled detectors. These systems allow the instrument to travel to the sample, which is advantageous where an archaeological object may not be able to travel to a laboratory due to size or fragility or other restrictions.

Key Issues/Current Debates/Future Directions/Examples

Within the area of archaeological and cultural heritage applications, several classes of material have had successful PIXE analysis and data interpretation. These include metals, obsidian, pigments, paintings, glass, ceramics, and other inorganic materials. A recent review article covers many of these materials and their analysis by PIXE (Beck 2014).

Ceramics are one of the first archaeological materials investigated by PIXE and have since expanded into archaeometric studies and applications worldwide. Some of the initial studies focused on bulk composition of ceramics and provenance studies. While provenance studies are still an important application of PIXE, some current papers are focusing more on surface applications and micro-PIXE of ceramic surfaces. An example of this is a recent paper by Polvorinos et al. that explores the application of PIXE understanding fourteenth- to eighteenth-century lustre glazes on Spanish ceramics including analysis of ceramic surfaces (Polvorinos et al. 2011).

PIXE has been applied to many types of archaeological metals, with coins and metal implements being the most common. There are many examples of compositional analysis of coins from many parts of the world and from many archaeological and historical periods. A recent article by Ben Abdelouahed et al. demonstrates the types of studies, analytical capabilities, and statistical analysis for coin analysis by PIXE (Abdelouahed et al. 2010).

Due to its near-surface capabilities, PIXE has been used widely in paint and pigment analysis. Neelmeijer et al. describe a combination XRF and PIXE methodology for studying the paint layers in modern sample as a case study for artworks. The authors use both methods for elemental analysis and depth profiling of the paint layers (Neelmeijer et al. 2000). PIXE analysis in this case offers valuable information on depth profiling by variation of the incident energy of the particle beam. Another recent study on pigment investigated the chemical composition of prehistoric pigments from Abri Pataud, France. The authors cite the nondestructive capabilities of PIXE as valuable for this application to rare prehistoric objects (Beck et al. 2011).

PIXE has also been applied to the characterization of archaeological obsidian objects. Composed of volcanic glass, obsidian can be characterized by its trace elemental signature, which reflects the material's origins. Other techniques such as NAA (neutron activation analysis) provide similar elements; however, the technique is usually destructive to the object as a sample must be cut from the original object. In contrast, PIXE can provide elemental data in a nondestructive method to the artifact. PIXE has been successfully used by Gazzola et al. to identify the original sources of obsidian found in Teotihuacan through elemental data and statistical interpretation (Gazzola et al. 2010). Berlot-Gurlet et al. provide a comprehensive comparison between PIXE, ICP-AES, and ICP-MS for the characterization of obsidian artifacts in a case study (Bellot-Gurlet et al. 2005).

A related application of PIXE to glass materials includes the analysis of archaeological and historical glasses. Elemental analysis by PIXE can be used to determine the major composition, and therefore, the original recipe of the glass. Trace elemental analysis can also be used to determine the provenance of the material. Calligaro presents a case study of archaeological and historical glasses, as well as the use of PIXE to study the surface modifications on glass (Calligaro 2008).

Recent advents in micro-PIXE have allowed insights into archaeological materials on much smaller scales than previously achieved by broader-beam PIXE instruments. While the technique allows higher spatial resolution, the time per analysis is longer due to the smaller beam size. Recent updates in technology have allowed micro-PIXE for use in extracted-beam setups as well. Torkiha et al. describe a laboratory set up of external micro-PIXE and its use on archaeological ceramics (Torkiha et al. 2010). The AGLAE facility at the Louvre routinely uses micro-PIXE for object analysis.

In the past decade, a group in Catania, Italy, has been developing a series of portable PIXE instruments based on polonium-210 radioactive sources for alpha particles. These instruments have been demonstrated on ceramics, coins, statuary, and other applications (Pappalardo et al. 2003; Rizzo et al. 2011). The portable capabilities of these instruments allow analysis of objects as well as frescoes and other materials that cannot travel.

Future developments include advances in instrumentation and electronics. Micro-PIXE analysis allows analysis on small scales previously not achievable with larger-beam diameters and the possibility of elemental "mapping" of an object surface. Coupled with external-beam facilities, this instrumentation allows microanalysis of objects without vacuum conditions, allowing analysis of objects of varied sizes and composition. PIXE in combination with Rutherford backscattering (RBS) analysis also offers information on the structure of the sample. REnct work describing a new system with a large solid angle improves the quantification of data obtained by PIXE (Pallon et al. 2017).

Faster and more compact electronics and detectors as well as alpha-source technology have allowed the expansion of portable PIXE technologies. Developments in this area will make portable PIXE instruments more widely available for archaeological and cultural heritage applications.
